Abstract

The main objective of this work was to develop a novel dimensionality reduction technique as a part of an integrated pattern recognition solution capable of identifying adulterants such as hazelnut oil in extra virgin olive oil at low percentages based on spectroscopic chemical fingerprints. A novel Continuous Locality Preserving Projections (CLPP) technique is proposed which allows the modelling of the continuous nature of the produced in-house admixtures as data series instead of discrete points. The maintenance of the continuous structure of the data manifold enables the better visualisation of this examined classification problem and facilitates the more accurate utilisation of the manifold for detecting the adulterants. The performance of the proposed technique is validated with two different spectroscopic techniques (Raman and Fourier transform infrared, FT-IR). In all cases studied, CLPP accompanied by k-Nearest Neighbors (kNN) algorithm was found to outperform any other state-of-the-art pattern recognition techniques.

Keywords: Continuous statistical modelling, dimensionality reduction, rapid detection, Adulteration, Extra virgin olive oil, FT-IR, RAMAN, spectroscopy

1. Introduction

The interdisciplinary collaborations between engineering, computer science and analytical science have led to the development of contemporary analytical instruments that allow the extraction of great amount of chemical information for a large number of samples relatively quickly and effortlessly. However, the produced analytical data (spectroscopic, chromatographic, isotopic, sensorial, etc.) are often multivariate data matrices which demand appropriate chemometric analysis. In chemometrics, mathematical and statistical methods are used for processing and capturing the most important and relevant content within the multivariate data. Despite the fact that a few multivariate methods are used in the area of food analysis either alone or in combination with other methods (Berrueta et al., 2007), there is an increasing demand for the introduction of novel and more intelligent pattern recognition methods for tackling more complex food analysis challenges such as food adulteration issues observed worldwide (Lohumi et al., 2015).

One of the most common adulterations occurring is mixing one commodity product or ingredient with another one in small percentages where the two ingredients are of a very similar chemical nature. In these cases, current chemometric techniques somehow fail to identify the fraudulent sample accurately (Ozen & Mauer, 2002; Šmejkalová & Piccolo, 2010) or use the same samples for both calibration and validation steps of the model (López-Díez et al., 2003; Christy et al., 2004), which biases the results. An indicative example of ongoing food fraud is the adulteration of extra virgin olive oil, a premium and high value commodity with renowned health properties (Zhang et al., 2011). Despite the establishment of a strict legislation framework, including specific analytical parameters defining the purity of the oil (International Olive Council, a; Agriculture and Rural Development, European Commission), the extra virgin olive oil adulteration with other lower value vegetable oils still remains

29 an important issue for the consumers and the olive oil sector alike (European
30 Commission, 2013; Frankel, 2010).

31 One of these adulterants is hazelnut oil, which has very similar triacylglyc-
32 erol, total sterol and fatty acid composition with extra virgin olive oil and has
33 concerned numerous researchers (Pena et al., 2005; Parker et al., 2014; Koidis &
34 Osorio Argüello, 2013). Extra virgin olive oil can be adulterated with hazelnut
35 oil in two different ways: adulteration with crude hazelnut oil and adulteration
36 with refined hazelnut oil. The identification of the adulteration with refined
37 hazelnut oil is increasingly difficult due to the removal of markers like filber-
38 stone, a volatile compound unique to hazelnut oil, and other minor components
39 through the refining process in addition to the similarity of the triacylglycerol
40 profile of both oils (Flores et al., 2006).

41 Most research efforts aiming to address this adulteration problem have made
42 use of chromatographic analytical methods. Despite providing satisfactory re-
43 sults by analysing the triacylglycerol content (International Olive Council, b),
44 polar components (Zabaras & Gordon, 2004) and using sterol fractions, 4,4'-
45 Dimethylsterols (Damirchi et al., 2005), n-alkanes (Webster et al., 2001) and
46 filberstone (Flores et al., 2006) as possible markers, chromatographic methods
47 involve complicated process steps, demand a large amount of time and financial
48 resources and require access to laboratory facilities. Therefore, it is urgent to
49 develop simple, inexpensive, rapid and accurate alternative methods to deter-
50 mine adulterants in extra virgin olive oil in environments that time and fast
51 decisions are important (ports, control points, market surveys and other rapid
52 testing environments).

53 Apart from chromatographic, several spectroscopic techniques in combina-
54 tion with chemometric methods have been proposed as rapid screening tech-
55 niques for the authentication of extra virgin olive oil and the detection and
56 quantification of its adulteration with hazelnut oil. Adulteration of olive oil
57 with hazelnut oil at levels of 25% and higher was detected using Fourier trans-
58 form infrared (FT-IR) coupled with partial least squares (PLS) analysis (Ozen
59 & Mauer, 2002). Moreover, the same combination has been used for devel-

60 opening a method for the estimation of extra virgin olive oil adulteration with
 61 edible oils including hazelnut oil. The produced PLS models for the case of the
 62 hazelnut oil showed a relatively good performance (relative error of prediction,
 63 REP=20.8 and correlation factor $R^2=0.9351$) (Maggio et al., 2010). Multiple
 64 linear regression (MLR) models constructed using FT-IR data for extra virgin
 65 olive oil-hazelnut oil admixtures claim to be capable of detecting hazelnut oil
 66 content in olive oil with a 5% limit of detection (Lerma-García et al., 2010).
 67 In another study, high gradient diffusion NMR spectroscopy coupled with dis-
 68 criminant analysis (DA) was used for detecting rapidly the adulteration of extra
 69 virgin olive oils with seed and nut oils. The lower limit of detection for the case
 70 of hazelnut oil was 30% (Šmejkalová & Piccolo, 2010). The development of an
 71 artificial neural network in 600MHz ^1H -NMR and ^{13}C -NMR data achieved a
 72 limit of 8% (García-González et al., 2004). In a recent study, 60MHz ^1H NMR
 73 spectral data in combination with PLS regression achieved a limit of detection
 74 at the level of 11.2% w/w (Parker et al., 2014). However, it has to be highlighted
 75 that the aforementioned studies tackling this adulteration of extra virgin olive
 76 oil with little or great success do not claim explicitly if the hazelnut oil is refined
 77 or crude and they are not often validated adequately and correctly which might
 78 produce overestimated and /or overfitted results.

79 The detection of adulterants at low levels (5-20%) is still quite challenging
 80 even for high end methods such as chromatography (Zhang et al., 2011; Osorio
 81 et al., 2014a). There is a need for more research in the field of data analysis
 82 of complex chemical data, especially spectroscopic data which are by nature
 83 multivariate. More accurate statistical methods are required to be used on
 84 top of existing analytical methods that would not necessarily demand a large
 85 number of samples and are independent of statistical interpretations (Frankel,
 86 2010).

87 The present work introduces a novel continuous statistical modelling tech-
 88 nique which extends the Locality Preserving Projections (LPP) dimensionality
 89 reduction technique to the cases where data are considered as a continuous vari-
 90 able. Data are modelled as data series and the continuity is preserved during

the learning and dimensionality reduction by building two graphs incorporating neighbourhood information of the data set. In this way, the proposed technique has been designed, developed and tested coupled with k-Nearest Neighbors (kNN) classifier on the adulteration of extra virgin olive oil with hazelnut oil using spectra from two different spectroscopic techniques. Preliminary results obtained are compared with the performance of state-of-the-art supervised pattern recognition techniques.

2. Theory and algorithm

2.1. The proposed method: Continuous Locality Preserving Projections (CLPP)

Continuous Locality Preserving Projections technique is a semi-supervised linear method that enables the dimensionality reduction for learning manifolds characterised by continuous data. It extends the linear dimensionality reduction technique LPP (He & Niyogi, 2003) preserving continuity as in previous non-linear techniques such as Temporal Laplacian Eigenmaps (TLE) (Lewandowski et al., 2010). LPP was chosen as the base method due to its properties and advantages against other dimensionality reduction techniques such as principal component analysis (PCA) (Wold et al., 1987) or linear discriminant analysis (LDA) (Fisher, 1938), especially when the input data show linear properties (He & Niyogi, 2003). Given a set of $Y = y_1, y_2, \dots, y_n$ data points in high dimensional space ($y_k \in R^D$) (see Fig. 1a), CLPP is able to transform this into its low dimensional space by mapping it to a set of points $Z = m_1, m_2, \dots, m_n$ ($m_k \in R^d$) with $d \ll D$ (see Fig. 1b), while preserving the continuity of the data.

CLPP algorithm includes the construction of two different neighbourhood graphs preserving implicitly the continuous similarity in data points during the space transformation. These graphs express continuous dependencies and therefore local continuous neighbours in the high dimensional space are located nearby in the embedded space without enforcing any artificial embedded geometry. Two continuous neighbourhoods are produced for each data point m_k (see

Fig. 2):

- Continuous neighbourhood (C_k): the $2t$ nearest points in sequence of current data point:

$$C_k \in \{m_{k-t}, \dots, m_k, \dots, m_{k+t}\} \quad (1)$$

- Similarity neighbourhood (S_k): the r points parallel to m_k , acquired from the r repetitions of m_k in the r parallel trajectories $T_{(1..r)}$. Each trajectory is generated by the $2t$ continuous neighbours:

$$S_k \in \{T_{k,1}, \dots, m_k, \dots, T_{k,r}\} \quad (2)$$

Specifically, the steps for the dimensionality reduction comprise:

1. Assign weights to the edges of each graph using the LPP formulation:

$$G_C(k, j) = \begin{cases} e^{-\|y^k - y^j\|^2}, & \mathbf{k}, \mathbf{j} \in C_k. \\ 0, & \text{otherwise.} \end{cases} \quad (3)$$

$$G_S(k, j) = \begin{cases} e^{-\|y^k - y^j\|^2}, & \mathbf{k}, \mathbf{j} \in S_k. \\ 0, & \text{otherwise.} \end{cases} \quad (4)$$

2. Compute the eigenvectors V of embedded space : The d eigenvectors V^* with the smallest nonzero eigenvalues make the embedded space. These eigenvectors and eigenvalues are calculated by solving the generalized eigenvalue problem:

$$\arg \min_{V^*} (V^T \cdot Y^T \cdot (L_C + \beta \cdot L_S) \cdot Y \cdot V) \quad (5)$$

subject to

$$V^T \cdot Y^T \cdot (D_C + \beta \cdot D_S) \cdot Y \cdot V = 1 \quad (6)$$

where $L_C = D_C - G_C$ and $L_S = D_S - G_S$ are the Laplacian matrices and D_C and D_S are diagonal matrices. β is a weighting factor for balancing the continuous and similarity variabilities.

CLPP applies the same principles than other continuous techniques that aim to preserve continuity (Lawrence, 2004; Lewandowski et al., 2010). Nevertheless, CLPP shows two main advantages regarding previous techniques: its simplicity and both directional mapping (from low to high and from high to low dimensional spaces) are provided automatically while reducing the space. This second advantage is crucial, since it has been proved that calculating those mappings from new data in non linear techniques is complex and inaccurate (Martinez-del Rincon et al., 2014). The linearity of the spectroscopic data as demonstrated by projecting them in a PCA space (Osorio et al., 2014b) proves the suitability of the CLPP to our application problem.

2.2. CLPP applied to oil adulteration

In order to apply CLPP framework to the extra virgin olive adulteration with hazelnut oil, it is important to understand how the raw data will be considered by the dimensionality reduction technique. Each adulterated olive oil sample will be considered as a data series T_r , where each data point m_k is the low dimensional representation of its corresponding spectra profile y_k at different percentage of adulteration from 0% to 100%, $k \in [0, 100]$. M_{k+t} and m_{k-t} , composing the subset C_k , will be then the same oils admixture but at the immediate higher and lower levels of adulteration correspondingly. S_k will be the set of different adulterated oils samples (different olive oil samples or the same olive oil sample but adulterated with a different hazelnut oil) adulteration at the exact same level of adulteration k (see Fig. 2).

Following these indications, our new CLPP technique has potential to be applied to any food authenticity problem involving admixtures and/or adulteration. In this paper, the adulteration of vegetable oils is used as the test case.

2.3. Projection of new testing samples into CLPP space

Due to its linearity, CLPP provides a simple mapping function for projecting new testing samples between high and low dimensional space. Equation 7

154 provides the mapping mechanism for a new testing sample $Y_{test} \notin Y$, whose
 155 classification we want to estimate:

$$Z_{test} = V^{*T} * (Y_{test} - \bar{Y}) \quad (7)$$

156 where $\bar{Y}$ is the mean value of the Y , learned during the creation of the latent
 157 space.

158 **3. Experimental results**

159 *3.1. Samples*

160 Four extra virgin olive oil samples consisting of three Italian (var. *Toscano*,
 161 *Olivastra Seggianese* and *Tonda Iblea*) and one Greek (var. *Koroneiki*), two
 162 Turkish refined hazelnut oils and two crude hazelnut oils (Turkey and Italy)
 163 were collected directly from the producers. The olive oil samples were spiked
 164 accurately at percentages that vary from 1% to 90%.

165 A few adulteration levels are necessary for generating the desired continuity
 166 in the produced latent space, as it can be noticed in Fig. 3, which illustrates
 167 the space resulted by LDA and CLPP by using different number of adulteration
 168 levels for FT-IR data. Specifically, sixteen different concentration grades were
 169 selected, from 1% to 15% with an interval of 2, and from 20% to 90% with an
 170 interval of 10 (see Table 1). The higher resolution in the low concentrations of
 171 hazelnut oil was selected in order to cover the most challenging adulteration area
 172 (5-20%) to detect (Zhang et al., 2011). A total of 256 admixture samples were
 173 prepared for Raman and FT-IR spectroscopic analysis (n=264 samples including
 174 the pure extra virgin olive oils, refined hazelnut oils and crude hazelnut oils),
 175 belonging to 16 possible combinations between the 4 base extra virgin olive oils
 176 and the 4 hazelnut oil adulterants.

177 *3.2. FT-IR/Raman spectral acquisition*

178 For FT-IR spectroscopic analysis, the acquisition of all FT-IR spectra was
 179 performed using a Nicolet iS5 Thermo spectrometer (Thermo Fisher Scientific,

180 Dublin, Ireland) equipped with a DTGS KBr detector and a KBr beam splitter.
 181 Spectra were acquired from 4000 to 550 cm^{-1} co-adding 32 interferograms
 182 at 4 cm^{-1} resolution with a diamond attenuated total reflectance (iD5 ATR)
 183 accessory. Absorbance values were recorded at each spectrum point. Three
 184 replicates resulting in 7157 variables were measured for each sample and the
 185 average spectrum of these was used.

186 A benchtop Advantage 1064 Raman Spectrometer (DeltaNu Inc., Laramie,
 187 Wyoming, USA) with a scanning range from 200 to 2000 cm^{-1} and an excitation
 188 light of 1064 nm was used to collect the Raman spectra of the oil samples. The
 189 integration time for each Raman spectrum was 10 s. The final sample spectra
 190 was the average of two replicates with initial 1867 data points.

191 3.3. Data pre-treatment

192 The resulting FT-IR and Raman spectral profiles underwent some typical
 193 preprocessing techniques in order to reduce or remove any random or systematic
 194 variation in the data (Devos et al., 2014). This phase involves three steps.
 195 Specifically, Standard Normal Variate (SNV) (Barnes et al., 1989) and S-Golay
 196 filter (Savitzky & Golay, 1964) [polynomial order=2, frame size=9] were applied
 197 for removing the scatter and smoothing the data points respectively. At the
 198 end of this preprocessing procedure, the irrelevant spectra area was cut out.
 199 Regarding FT-IR, data fall between 690.39 and 1875.434 cm^{-1} and between
 200 2750.476 and 3100.01 cm^{-1} which result in a spectrum of 3184 variables. In
 201 Raman dataset, 1038 variables between 800.314 and 1800.22 cm^{-1} were selected.

202 All chemometric data preprocessing was performed by means of in-house
 203 Matlab routines (The MathWorks Inc., USA).

204 3.4. Experimental setup

205 The performance of the proposed dimensionality reduction technique as
 206 part of a classification technique is evaluated by comparing it with the most
 207 used supervised pattern recognition techniques in the literature of food science
 208 (Berrueta et al., 2007), i.e. soft independent modelling of class analogy (SIMCA)

209 as the modelling method, partial least squares discriminant analysis (PLS-DA),
 210 kNN and nearest neighbour using Pearson’s correlation for distance metric as
 211 discriminant methods, partial least squares (PLSR) (Wold et al., 1984) as the
 212 regression technique and unsupervised hierarchical clustering (UHC) (Di Giro-
 213 lamo et al., 2015) as an unsupervised learning technique. It is also compared
 214 against other pattern recognition techniques that we consider they have poten-
 215 tial to tackle the adulteration problem. These were PCA + kNN, LDA + kNN
 216 and LDA + support vector machines (SVM) (Belousov et al., 2002) as discrim-
 217 inant methods. It has to be mentioned that the methodologies involving LDA
 218 also required PCA to be applied before LDA to reduce the dimensionality for
 219 solving LDA’s limitation on a low sample-to-variable ratio (number of samples
 220 $\ll$ number of variables) (Szymańska et al., 2015). Parameter tuning was opti-
 221 mised empirically for every technique within the comparison in order to provide
 222 the highest classification rate in each of them. Details about the parameters
 223 values used in our measurements for gathering results are shown in the supple-
 224 mentary material. For CLPP, $t=3$ and $r=5$ were used in all experiments. It has
 225 to be noted that CLPP is a novel method that was conceived and developed by
 226 this research team and directly implemented in Matlab.

227 The main proposal of this work is the application of kNN on the CLPP space.
 228 CLPP has been also combined and tested with SVM, geodesic distance, clus-
 229 tering and Mahalanobis distance as classifiers for finding the best combination
 230 (data not shown). Furthermore, PLSR is applied in combination with the CLPP
 231 latent space for exploring the potential improvement regarding the conventional
 232 PLSR. The rationale of this experiment is that applying regression on a low di-
 233 mensional space is simpler and computationally less expensive than on the raw
 234 data while preserving the advantages of regression outputs. For comparison
 235 purposes, the application of PLSR on PCA space was also examined.

236 As previously mentioned, two spectral datasets (Raman and FT-IR spec-
 237 tra) of 256 samples each were investigated for this work. It is accepted that to
 238 evaluate the classification ability of all the aforementioned multivariate tech-
 239 niques, the testing dataset must not be used in the building of the model

(Biancolillo et al., 2014). Therefore, experiments were conducted using leave-one-adulterated-oil-out cross validation in which two oils, one of the four extra virgin olive oils and one of the four hazelnut oils (crude or refined) and all their admixtures are taken for testing leaving the rest of them for the training of the model in each iteration. In total, sixteen iterations were performed for each experiment. Admixtures of the two testing oils with the remaining training oils are not used at all in the experiment iteration for producing unbiased, generalised and realistic results. This leads to training and testing sets consist of 168 samples and 18 samples respectively in each iteration.

The mean accuracy and the standard deviation over these iterations are the main evaluation metrics of this comparative analysis. Root mean square error (RMSE) of prediction was measured for the cases in continuous space (PLSR, PCA + PLSR and CLPP + PLSR) given the continuous nature of their output as an adulteration percentage in real numbers. For computing the classification rate for the PLSR experiments, if the PLSR output value of a testing sample is within the range of adulteration associated to a given class then this sample is classified to this specific class.

Two different classification scenarios on the adulteration of olive oil with hazelnut oil are considered with respect to the number of classes for establishing a clear idea of the behaviour of the compared techniques. Here the concept of the class is related to the expected level of resolution to be detected in the adulteration. The eighteen concentration grades (the 16 adulteration levels shown in Table 1 plus pure olive and pure hazelnut oil) of the in-house admixtures were grouped in 10 classes (1st class $\in [0,1)$, 2nd class $\in [1,5)$, 3rd class $\in [5,9)$, 4th class $\in [9,13)$, 5th class $\in [13,20)$, 6th class $\in [20,40)$, 7th class $\in [40,60)$, 8th class $\in [60,80)$, 9th class $\in [80,90)$, 10th class $\in [90,100]$), where the numbers in the intervals represent the concentration of hazelnut oil within the mixture, in percentage. These classes were used for the calibration and validation of the model in a first scenario. Thereafter, the characterisation of a spectrum of an oil sample as pure extra virgin olive oil ($\in [0,1)$), low adulterated extra virgin olive oil ($\in [1,12)$), high adulterated extra virgin olive oil ($\in [12,90)$) and mostly

271 pure hazelnut oil ($\in [90,100]$) (4 classes) is addressed to the second scenario.
 272 This second scenario aims to evaluate the performance of our methodology in
 273 an adulteration screening system, where a simple decision is intended.

274 3.5. Discussion of the results

275 3.5.1. Qualitative analysis

276 An exploratory representation for FT-IR data is presented in Fig. 4 us-
 277 ing PCA, LDA and CLPP with two latent dimensions. All three dimension-
 278 ality reduction techniques were performed using the same values for the pa-
 279 rameters for both scenarios (PCA: PCA_dims=2; LDA: LDA_dims=2; CLPP:
 280 CLPP_dims=2, $\beta=0.50$). The pattern of the mapped data of PCA and CLPP
 281 spaces remains similar in both scenarios. It appears that PCA, as an unsuper-
 282 vised dimensionality reduction technique, does not allow a clear separation of
 283 the admixtures for FT-IR data for all cases. Unlike PCA, admixtures are more
 284 discriminant in LDA space due to the pronounced supervised class membership.
 285 On the other hand, CLPP provides a better visualisation and dispersion of the
 286 continuous data. Specifically, it can be noticed that pure olive oils and hazelnut
 287 oils are plotted on the extremes of the produced CLPP arc respectively, whereas
 288 the different admixtures are lied across the arc that prove the data continuity.
 289 Similar conclusions can be drawn for Raman data (Figures not shown).

290 3.5.2. Quantitative analysis

291 The cross validation schema was applied as described in section 3.4 for two
 292 examined scenarios.

293 *Classification problem with 10 classes.* Table 2 presents the mean classification
 294 rate and the standard deviation of each pattern recognition technique. Only
 295 LDA and CLPP perform above the state-of-the-art techniques, i.e. SIMCA and
 296 PLS-DA in both Raman and FT-IR data. In spite of the difficulty and the
 297 complexity of this scenario, CLPP+kNN shows the best performance in both
 298 datasets regarding classification rate and standard deviation, obtaining around
 299 40% of recognition rate of the adulteration level. In addition, the application

of CLPP on a PLSR framework performs better than the simple PLSR, which proves further the suitability of the CLPP reduced space to the adulteration problem. PLSR execution also exhibits a parallel reduction in the error of prediction (RMSE reducing from 0.19 to 0.18 for Raman spectral data and from 0.22 to 0.20 for FT-IR). PLSR on PCA space improves the classification ability of PLSR only using RAMAN spectra by retaining the same RMSE.

Classification problem with 4 classes. The decrease in the number of classes influences the classification considerably as it can be seen in Table 2. Using four different groups of classes, roughly 79% and 75% correct classification can be achieved with CLPP+kNN (see Table 2) in RAMAN and FT-IR respectively, being the best performing algorithm and with the smaller standard deviation (cross validation). Regardless of the number of classes in the problem, CLPP+PLSR enhances the performance of the simple PLSR in satisfied levels with simultaneous decrease in RMSE, from 0.23 to 0.18 for Raman and from 0.24 to 0.19 for FT-IR data. PCA+PLSR also improves the general PLSR performance and the RMSE (to 0.19 for Raman and to 0.20 for FT-IR), although in a smaller amount. Furthermore, an extra column has been included for indicating the classification ability of each technique in low percentages (1-12%) since this area is the most challenging for most analytical methods and particularly for rapid screening applications such as the current one. For the case of 10 classes, this area (1-12%) is not applicable since the number of classes provide already a more detailed partitioning. SIMCA exhibits a very low classification rate of 12.50% for Raman data because according to the literature it is very sensitive to handle unbalanced training datasets and classifies most testing samples to the class with the more representatives (12-90% hazelnut oil adulteration) (Alonso-Salces et al., 2010). CLPP+kNN exhibits again the highest performance in this measure for both datasets.

Referring to both scenarios, the option to model the adulteration of extra virgin olive oil with both crude hazelnut oil and refined hazelnut oil at the same time and the relatively small number of pure samples make the problem more

330 complicated and challenging but also demonstrate clearly the great potential
 331 of CLPP technique. Beyond the performance of CLPP+kNN, the classification
 332 ability of the application of PLSR on CLPP space is better compared with the
 333 simple PLSR and the qualitative analysis of the space is more continuous and
 334 coherent with the true nature of the data. In the first scenario, LDA+kNN and
 335 PCA+kNN produce comparable results with CLPP+kNN in some particular
 336 case. Although the difference between their performance is not statistical sig-
 337 nificant, since their error bars (see supplementary material) overlap i.e. P value
 338 > 0.05 (Cumming et al., 2007), CLPP+kNN is consistently more accurate and
 339 with smaller standard deviation in the most of the cases investigated. This can
 340 be justified from the systematic design of the training sample set that we de-
 341 signed and that allows the resulting latent space produced by LDA and PCA
 342 to become convergent to CLPP when the number of classes is large (see Fig.
 343 4). Notably, the most widely applied and leading multivariate techniques like
 344 SIMCA, PLS-DA and PLSR, exhibit the weakest results in the condition of the
 345 first scenario where a ten classes classification problem is examined.

346 **4. Conclusions**

347 In this paper, a dimensionality reduction technique was developed to model
 348 the continuous nature of the admixtures as data series for addressing the adulter-
 349 ation of extra virgin olive oil with hazelnut oil. The food adulteration problem
 350 was modelled in two separate ways with a different number of classes. The
 351 results proved that CLPP coupled with kNN provides the best classification
 352 performance compared to state-of-the-art techniques (SIMCA, PLS-DA). This
 353 study confirms that the proposed solution could be very useful and effective for
 354 screening purposes. About 80% and 75% overall mean classification rate was
 355 obtained for the classification problem with four classes with more than 82%
 356 and 69% in low percentages (1%-12%) for Raman and FT-IR data respectively.
 357 Moreover, some interest remarks for the scientific chemometric community can
 358 be derived from this work. First, the adulteration problem is continuous by

359 nature and should be considered as such in the next generation chemometric
360 analytic tools, as revealed by the low performance of current pattern recogni-
361 tion techniques and the improvement in performance when combining CLPP
362 with PLSR in all investigated cases. Second, a detailed data with high number
363 of samples and/or publicly available datasets for model training is crucial for
364 developing new algorithms for tackling adulteration problems as evidenced by
365 the good performance provided by LDA when samples were carefully prepared.
366 Bearing in mind that this type of olive oil adulteration is a sophisticated and
367 difficult analytical problem, this preliminary study demonstrates clearly that
368 CLPP-based framework is able to preserve the continuous nature of the data
369 that can be used for screening purposes on low adulteration olive oil mixtures.

370 Future work will look at the application of CLPP to other challenging food
371 adulteration problems such as the authenticity of dairy powder and of herbs
372 and spices, using FT-IR, Raman spectroscopic data, given CLPP's theoretic-
373 al potential to be applied to any admixture problem, and higher number of
374 samples.

Figure 1: Definition and application of CLPP: (a) Data points in high dimensional space; (b) Data points in low dimensional space.

Figure 2: Continuous neighbours of a given sample, m_k : continuous (orange points) and similarity neighbours (green points).

Figure 3: LDA space produced by FT-IR for: (a) three adulteration grades; (c) six adulteration grades. CLPP space for FT-IR data: (b) three adulteration grades; (d) six adulteration grades (see legend). EVOO, extra virgin olive oil; HO, hazelnut oil.

Figure 4: Exploratory analysis of FT-IR data for 10 classes: (a) PCA score plot; (b) LDA space; (c) CLPP space. For 4 classes: (d) PCA score plot; (e) LDA space; (f) CLPP space. EVOO, extra virgin olive oil; HO, hazelnut oil.

Table 1: Details of extra virgin olive and hazelnut oils for Raman and FT-IR analysis.

Admixtures		
Identity of the reference olive oil	Identity of the adulterant hazelnut oil	Concentration (%v/v) of hazelnut oil
EVOO1	RHO1	1.00
		3.00
		5.00
		7.00
		9.00
EVOO2	RHO2	11.00
		13.00
		15.00
		20.00
		30.00
EVOO3	CHO1	40.00
		50.00
		60.00
		70.00
EVOO4	CHO2	80.00
		90.00

'EVOO' indicates extra virgin olive oil; 'RHO' is refined hazelnut oil and 'CHO' is crude hazelnut oil.

Table 2: Mean classification rate (%) and standard deviations of the testing samples within each dataset for 10 different classes and for 4 percentage areas for the detection of olive oil adulteration using RAMAN and FT-IR.

CLASSIFICATION	RAMAN		FT-IR	
TECHNIQUE	Overall (%)	For 1-12%	Overall(%)	For 1-12%
For 10 different classes
