17 Abstract

Management of wildlife is often a contentious issue in which stakeholders are increasingly 18 influential. The European hare (Lepus europaeus) is a non-native, invasive species, now 19 established in Northern Ireland. It impacts the endemic Irish hare (L. timidus hibernicus), a 20 priority species of conservation concern, via competition and hybridisation to the extent that 21 control of European hares is a priority. We conducted a questionnaire survey among members of 22 23 Countryside Alliance Ireland [CAI] - an organisation that promotes rural interests, including 24 field sports - and non-members, to ascertain the contrasting attitudes to the lethal control of European hares in Northern Ireland; a total of 342 (20%) questionnaires were returned. We 25 hypothesised that: (i) CAI members would exhibit greater support for intervention than non-26 27 members; and (ii) respondents in the core invasive range will differ in their outlook when compared to respondents from other zones. CAI members were more likely to be aware of the 28 presence of the non-native species and to support lethal management. Both groups considered the 29 30 threat posed to biodiversity by the European hare to be important. We conclude that members of rural interest groups may be important advocates of intervention, whilst non-members of field 31 32 sports organisations may be more reluctant to support any proposed management plan involving lethal control. Active engagement to develop a mutual understanding, prior to developing 33 management options, is crucial in ensuring long-term success. 34

35

37 Introduction

The European brown hare (Lepus europaeus, Pallas 1837), is not native to Ireland, having 38 been introduced during the 1800s for field sports (Barrett-Hamilton, 1898). Populations 39 persist in Mid-Ulster and west Tyrone (Reid & Montgomery, 2007); despite historical records 40 in Donegal there are no verified extant populations in the Republic of Ireland. The native 41 Irish hare (Lepus timidus hibernicus, Bell 1837), an endemic sub-species of mountain hare (L. 42 timidus, Linnaeus 1758), is one of the few Irish mammals that pre-date the Holocene 43 (Montgomery et al., 2014), having been isolated for at least 28,000 years (Yalden, 1999; 44 45 Clark et al., 2012). Irish hare populations, which underwent a prolonged decline throughout the 20th century (Dingerkus & Montgomery, 2002; Reid et al., 2010), are now a high priority 46 for conservation action. The range of the European hare in Mid-Ulster expanded threefold 47 48 between 2005 and 2013 (Caravaggi et al., 2015), with the Irish hare almost entirely displaced from the invader's core range (Caravaggi et al., 2016). Furthermore, the most recent data 49 describe extensive hybridisation between the native and the invader in the invader's range, 50 with 32% of individuals being of hybrid origin (Prodöhl et al., 2013). The Irish hare is 51 protected under Schedule 6 of the Wildlife (Northern Ireland) Order (1985), the Wildlife and 52 Natural Environment Act (Northern Ireland; 2011), the Convention on Biological Diversity 53 (UNEP, 1992), the Berne Convention (Berne, 1979) and the European Habitats Directive, 54 Annex V (EEC, 1992). In addition, the recently ratified EU Regulation 1143/2014 on 55 56 Invasive Alien Species (OJ, 2014) commits member states - in this case the United Kingdom, including Northern Ireland, and the Republic of Ireland - to identify invasive species issues 57 and work to protect native biodiversity. 58

Rapid threat identification and eradication offers the most effective means of management
and mitigation (United Nations Environment Programme [UNEP], 1992). However, once
biological invaders become established, control and/or eradication is often difficult, if not

impossible (Zavaleta et al., 2001). Nevertheless, invasive mammals can be eradicated, even if 62 they are relatively well-established. Most successful removals have been undertaken on 63 islands (Genovesi, 2005; e.g. Clout & Russell, 2006; Donlan et al., 2007; Aguirre-Muñoz et 64 al., 2008). A number of invasive mammal species have been successfully eradicated from all 65 or parts of Great Britain and/or Ireland, including American mink (Neovison vison; Moore et 66 al., 2003) and Himalayan porcupine (Hystrix brachvura; Genovesi, 2005), as well as 67 commensal rodents, rabbits and goats from small offshore islands (e.g. Flux, 1993; Lock, 68 2006; Database of Island Invasive Species Eradications [DIISE], 2015). Covpu (Myocastor 69 70 coypus), semi-aquatic rodents native to South America, escaped from fur farms in England and established a wild population of up to 200,000 individuals during the 1960s before being 71 removed during the 1980s (Baker, 2006). Similarly, the muskrat (Ondatra zibethica), was 72 successfully eradicated from Ireland (Fairley, 1982) and Great Britain (Warwick, 1941) by 73 1936 whilst introduced roe deer (Capreolus capreolus) were eradicated from Ireland in the 74 early 20th century (Fairley, 1984, 2001). 75

76 Wildlife control, however, has become a contentious issue in which the public are increasingly influential. A lack of public support can impact the efficacy of eradication 77 campaigns, reducing the probability of success (sensu Enticott, 2015; McCagh et al., 2015). It 78 is increasingly important, therefore, to garner public support for initiatives involving the 79 removal or translocation of wildlife (Bremner & Park, 2007; Philip & Macmillan, 2005; 80 Sijtsma et al., 2012). Eradication programmes in particular, can often be perceived as 81 objectionable, and ethically challenging (Manchester & Bullock, 2001; Bertolino & 82 Genovesi, 2003). However, while the views of professionals (i.e. ecological experts) and the 83 public may differ with regards to invasive species, there are also many commonalities (Roux 84 et al., 2006; Buijs & Elands, 2013; Fischer et al., 2014). Thus, the assumptions of the 85 'deficit-model', wherein the public are described in general terms as a homogenous body 86

87 requiring education (usually by scientists) are increasingly seen as antiquated and limiting 88 (Fischer *et al.*, 2014). It is essential, therefore, that decision makers and those implementing 89 population management policies have a sound understanding of different perspectives on 90 invasive species issues, thus facilitating the development of socially acceptable solutions. 91 Discussion and transparency between all parties prior to the application of control 92 programmes may offset what might otherwise be perceived as unpalatable management 93 prescriptions, and mitigate against potential conflict (Fischer *et al.*, 2014).

Given the increasing role of the public in participatory decision making and the legal 94 95 requirements for government in both political jurisdictions of Ireland to address invasive species issues, it is important that decision makers have a sound understanding of public 96 attitudes on which they can base management decisions. We aimed to ascertain the degree of 97 98 awareness and explore local views on the management of the European hare in Northern Ireland. Specifically, we tested the hypothesis that members of Countryside Alliance Ireland 99 (CAI) - an organisation that promotes rural interests, including field sports (e.g. hunting, 100 shooting (see www.caireland.org)) - may exhibit greater support for intervention than non-101 members. We also compared responses across three geographic zones: native species 102 allopatry; and the invasive species' peripheral and core ranges. We hypothesised that 103 respondents in the core range where European hares have almost entirely displaced the native 104 species will differ in their outlook to respondents in other zones. The results presented are 105 likely to inform the development and adoption of government policy and any subsequent 106 management programme for the European hare in both political jurisdictions of Ireland, and 107 could act as a model for the management and/or control of comparable invasive species 108 109 elsewhere.

111 Methods

A questionnaire (Supplementary Information (SI) 1) was used to assess public awareness of 112 the European hare as an invasive species, and the willingness of the public to support direct, 113 interventionist management. Questions were descriptive (i.e. more than two options were 114 provided, or a textual response was required) or discrete (i.e. only two options were provided: 115 116 yes or no). A total of 1,680 questionnaires were issued by post in August 2014, to two groups across Northern Ireland: CAI members, and non-members. No inducements were offered to 117 encourage responses. The CAI defines itself as "promot[ing] the interests of rural people, 118 including all field sports (hunting, shooting, fishing, falconry, ferreting, coursing, stalking 119 etc), sensible wildlife management, and wider countryside concerns such as jobs, landscapes 120 and freedoms". Non-members were defined as randomly-selected participants (see below) 121 whose address did not correspond with that of any then-current CAI member. Survey 122 participants were further selected according to their geographic location relative to minimum 123 convex polygons (MCP) that described the core (50% occurrence) and peripheral (100% 124 occurrence) range of the invasive European hare in 2012-13, with the zone of native Irish 125 hare allopatry occurring outside the peripheral polygon (Fig. 1a). MCPs were mapped using 126 ArcGIS 10.3.1. For further details on how these zones were delineated, see Caravaggi et al. 127 (2015). In total, 280 questionnaires were sent to each of 6 sub-groups (Fig. 2). 128

Respondents were randomly selected within 5 km radii of a number of focal settlements, within each zone of invasion, so as to provide a widespread geographical sample (Fig. 1a). The closest dwelling to randomly generated waypoints within each 5km buffer was identified using Google Maps, and the address recorded. Questionnaires were distributed by CAI to randomly-selected members within the same settlements so as to comply with the Data Protection Act and issues regarding the protection of names, private details and addresses.

Thus, it was not possible to account for demographic factors such as age, gender and income. 135 The number of focal settlements per zone was defined by two factors. First, settlements were 136 required to have a population >400 to ensure presence of CAI members (whilst avoiding 137 large towns or cities of >12,000). Mean population size per settlement per zone were 138 comparable, with 2,899 \pm 1,833 people in the invader's core range, 2,749 \pm 1,142 in the 139 invader's peripheral range and $2,683 \pm 553$ people in the zone of native allopatry. The second 140 factor was to ensure that the total number of CAI members per zone was in relative 141 proportion to the mean population. The number of potential recipient settlements in the core 142 143 and peripheral zones was limited by the small geographic extent of the invasive range. Thus, four settlements were selected in the invader's core range, nine in the invader's peripheral 144 range and thirteen in the zone of native allopatry (Fig. 1a). 145

The survey questionnaire (see SI 1) was developed in association with the Department of 146 Agriculture, Environment and Rural Affairs (DAERA), the agency that would be responsible 147 for sanctioning any invasive species population intervention. Each questionnaire was given a 148 unique reference number. All respondents were anonymous unless they elected to provide 149 contact details. Electronic questionnaires were unsuitable for our purposes given the rural 150 151 locations and lack of broadband internet for many respondents. Questions 1-7 ascertained the respondent's occupation and general attitudes towards hares and were followed by an 152 153 information page regarding the threat posed by the invasive species (based on peer-reviewed published information), thereby ensuring that respondents were able to place subsequent 154 questions in an appropriately informed context. Questions 8-20 clarified prior awareness of 155 invasive species issues, examined attitudes post-information provision, and sought opinion of 156 157 population management i.e. whether participants would support government intervention to benefit the native species. Question 20 was deliberately circular, repeating a query on 158 willingness to support a cull (Q13b) but framed in the context of supporting a government 159

decision. These responses were used as an indicator of respondent consistency, or lack 160 thereof. Differences between responder groups were assessed using binomial tests where a p-161 value is derived from comparing observed and expected values for given sample sizes. An 162 Analysis of Variance (ANOVA) test, with Tukey post-hoc tests, was used to determine 163 differences in levels of support for lethal culling between respondent groups in each of the 164 three study zones. Confidence intervals of 95% around percentage data were established by 165 calculating the Wilson interval without correction for continuity (Wilson, 1927, as described 166 in Newcombe, 1998). Pearson's correlation coefficient was used to investigate relationships 167 168 between certain questions (e.g. Q13b and Q17). Textual responses ('Additional comments', SI 1) were analysed based on their perceived support for lethal management, or lack thereof 169 (applied categories: yes; no; unsure). 170

A General Linear Model (GLM) was constructed with support for lethal management (0/1)171 fitted as the dependant variable using a binomial error structure and a logit link function. Six 172 questions (10; 13a; 15; 18; 19) were omitted as fewer than 90% of respondents completed the 173 answers, substantially reducing the sample size available for analyses (n = 215 - 307). The 174 effect size of each variable in the top model (see SI 2) was plotted and variables ranked by 175 their effect. The Area Under the Curve (AUC) of the Receiver Operating Characteristic 176 (ROC) curve was used to assess the performance of the single best approximating model. All 177 statistical analyses were run in R (R Core Team, 2017) using the packages leaps (Lumley, 178 2009), MuMIN (Barton, 2015) and pROC (Robin et al., 2011). 179

181 **Results**

A total of 342 questionnaires were returned (20% response rate), of which 140 were from 182 CAI members (41%), and 202 were from non-members (59%). Response rates from non-183 members were comparable between the zones of invasion with 35% in Irish hare allopatry, 184 34% in the invader's periphery and 31% in the invader's core range. In contrast, response 185 186 rates from CAI members were significantly higher within the invader's core range (41%) compared to the invader's periphery (31%; p < 0.001) and the zone of Irish hare allopatry 187 (28%; p < 0.001). Landowners accounted for 77% of non-members, with 91% having 188 observed hares, whilst landownership was lower among CAI members (51%; p < 0.001), of 189 whom 99% had observed hares (Table 1). 190

191 CAI members were significantly more likely to provide textual comments with their 192 responses (38%) compared to non-members (13%; p < 0.001; SI 3). The majority of 193 comments concerned lethal management of the European hare (68% vs 59% of CAI members 194 and non-members respectively), of which 44% of respondents indicated their opposition, 195 irrespective of affiliation; 25% of CAI member respondents would support a cull (vs 12% of 196 non-members), and 31% were unsure (vs 44% of non-members).

The majority of respondents perceived that the hare population (both species) had declined 197 during the last 50 years (66% of respondents), while 49% maintained that this decline was 198 ongoing during the last 5 years (Fig. 3). The most notable differences in opinion were held by 199 those who perceived population trajectories to be increasing during the last 50 years, with 200 19% of CAI members, compared to 8% of non-members (p < 0.001). CAI members were less 201 202 likely to consider hares an agricultural pest than non-members. Respondents from all three zones of invasion (including Irish hare allopatry) claimed to have observed European hares, 203 contradicting the known (observed) range of the invasive species (Fig. 1b). 204

CAI members were significantly more likely to have been aware of the presence of the 205 invasive species prior to receipt of the questionnaire than non-members (62% vs 29% 206 respectively; p < 0.001), and to support active petitioning of government for control of the 207 invader than non-members (60% vs 37% respectively; p < 0.001; Table 1). Levels of support 208 for lethal control differed between the two groups, with CAI members being more likely to 209 support culling than non-members (66% vs 40% respectively; p < 0.001; Fig. 4a; Table 1). 210 An ANOVA with Tukey *post-hoc* tests captured significant differences between the opinions 211 of respondent groups between the zones of invasion. CAI members resident in the invader's 212 213 peripheral range were significantly more likely to support a cull than non-members anywhere within the invader's range (core or periphery), whilst CAI members in the zone of native 214 allopatry were more likely to support a cull than non-members (Fig. 4b). 215

CAI members were significantly more likely to hunt than non-members (91% vs 21% 216 respectively), with support for lethal culling being strongly correlated with hunting activity (r 217 = 0.54, p<0.001). A large proportion of respondents who owned or rented land would permit 218 a hare population survey to be carried out (83%; Fig. 5). However, those with smaller 219 properties (<30 ha) were less likely than those with larger properties (30-100 ha and >100 ha) 220 to permit European hares to be lethally removed if they were found to be present (42% vs 221 56% respectively; p = 0.007; Fig. 5). Both groups (i.e. members and non-members) 222 223 responded similarly to questions relating to their concern for the conservation of biodiversity with 82% of CAI members and 88% of non-members 'concerned'. Similarly, both groups 224 had comparable willingness to support impact mitigation (81% vs 76% respectively) and/or 225 habitat management for the benefit of the native species (78% vs 80% respectively; Table 1). 226

Responses to questions 13b (support for lethal management of the European hare) and 20
(support for a government decision to cull) demonstrated considerable respondent

consistency, with 82% (n = 138) of CAI members and 90% (n = 123) of non-members providing consistent answers. The single best approximating model for support of lethal management was influenced by the respondent's willingness (or lack thereof) to petition government (Q14), and whether the respondent supported management (Q12), hunted (Q17), was aware that there were two species of hare in Northern Ireland (Q8), and was concerned with the conservation of biodiversity (Q3; Table 2; Fig. S2.1).

236 Discussion

This study is the first quantitative investigation of public attitudes to management of the 237 European hare population in Northern Ireland. The response rate to our survey (20%) was 238 considerably lower than the mean response rate ($52 \pm 3\%$) reported from a meta-analysis of 239 82 postal ecological surveys (White et al., 2005). A stratified random sampling procedure 240 was used to minimise bias, but our data have inherent limitations with regards to 241 demographic representation; a common problem in questionnaire-based research (Sapsford, 242 1999). The lower than anticipated response rate may reflect unquantified factors, including: 243 low motivation of targeted households; apathy with regards to wildlife management and/or 244 conservation; lack of identification with a remote government and/or study; a lack of 245 engagement (e.g. disposal of the questionnaire); and, distrust of authority figures (i.e. 246 government, scientists, etc.). Opinions on wildlife control methods are also likely to vary 247 according to gender, age, income and education (Koval & Mertig, 2004; Bremner & Park, 248 2007; Enticott, 2015). This was probably also true in the present study, but demographic data 249 were lacking due to the necessity to anonymise questionnaires (at the request of CAI) for data 250 protection. 251

252 Fraser et al. (2014) suggested that stakeholders with a vested interest in their environment, such as voluntary participants, or those with an economic interest such as farmers and land 253 managers that subscribe to agri-environment schemes (e.g. the Environmental Farming 254 Scheme; DAERA, 2017), may be more willing to actively help protect local biodiversity. 255 However, public opinion with regard to non-native species is not necessarily predictable 256 (Koval & Mertig 2004); while the reasoning of experts and the public share common 257 258 linkages, they do not necessarily arrive at the same decisions (Buijs & Elands, 2013; Fischer et al., 2014). Hence, the acceptability of management prescriptions is likely to vary on a case-259 by-case basis. This is reflected in the present study, with both groups being in agreement on 260

many questions, but differing in their support for lethal management (66% CAI vs 40% of non-members). The responses of non-members to potential management options suggest that lethal control may only be considered acceptable once other methods have failed (Dandy *et al.*, 2011, 2012). However, Enticott (2015) suggests that public support may be influenced by framing the issue appropriately, in this case, the protection of a unique, endemic species.

The lowest levels of support for lethal control in both respondent groups were found in the 266 invader's core range, where European hares occur at a high density to the near total exclusion 267 of the Irish hare (Caravaggi et al., 2016). This raises the possibility that exposure to the 268 269 invader does not necessarily confer support for lethal management (Dandy et al., 2011). Indeed, the perception of the species may depend not on its nativeness, or lack thereof, but on 270 the composition of the local ecological assemblage. Therefore, control or eradication of the 271 272 European hare may not be perceived as necessary in the invasive core range where the native species is largely absent. This rationale may be interpreted in terms of functionalism (i.e. the 273 retention of ecosystem processes) versus compositionalism (i.e. maintaining species 274 assemblages; Callicott et al., 1999; Gillson et al., 2011) whereby the local ecosystem still has 275 hares, that may carry out the same ecological functions of grazing and being key prey, and at 276 a higher density than before (Reid & Montgomery, 2007; Caravaggi et al., 2016). Differences 277 in the acceptability of lethal control may also depend on the type and volume of information 278 279 available on invasive species and conservation options for the native post-removal (e.g. 280 natural recolonization, anthropogenic translocations). To address these questions, it would be beneficial to engage in a dialogue with stakeholders so as to arrive at a mutual understanding, 281 prior to considering management options (sensu Fischer et al., 2014). 282

The picture may be complicated when sympatric native and invasive species are phenotypically similar, as untrained observers may be unable to differentiate between the two (COI, 2009). Indeed, this seems to be the case in the present study; most European hare

records (n = 79; 75%) were returned within the invader's range in Mid-Ulster, while the 286 remainder were distributed across Northern Ireland, in localities far beyond their known 287 range, where they were previously undetected by surveyors (Reid & Montgomery, 2007; 288 Caravaggi et al., 2015, 2016; Fig. 1b). It is possible that European hares have been observed 289 by the public where they were missed by surveyors; hare survey data from nocturnal distance 290 sampling are spatially broad, but temporally narrow, with observations being affected by 291 undulating terrain, and surveys were not comprehensive. However, while a number of 292 putative European hare observations have been recorded across Ireland, none have been 293 294 substantiated (Reid, 2011; Caravaggi, 2012-15, pers obs). Thus, we can be relatively confident that most records from outside the known range in the present study were based on 295 inaccurate observations/recollections and species misidentification. 296

Irish hare populations declined dramatically throughout the 20th century (Dingerkus, 1997; 297 Dingerkus & Montgomery, 2002; Reid, 2006; Reid et al., 2006), but stabilised during the 298 early 21st century at low densities (Reid et al., 2007). European hares may have been 299 introduced to Mid-Ulster as recently as the 1970s with subsequent population and range 300 expansion, most notably between 2005 and 2012/13 (Caravaggi et al., 2015). Hare population 301 densities are up to eight times higher in the invasive core range than in areas of Irish hare 302 allopatry, with over 90% being European-like (Caravaggi et al., 2016). Thus, we might have 303 expected questionnaire respondents to corroborate these observations, particularly within the 304 305 invasive core range. However, while more respondents considered hare numbers to have stabilised in the last 5 years (33%) when compared to the last 50 years (22%), there was no 306 difference in the number of respondents who perceived a short-term population increase in 307 the core range of the European hare. Public observations, therefore, while undoubtedly 308 valuable in providing contemporary occurrence records for wildlife, may be less reliable 309

when it comes to assessing more subtle events such as population fluctuations, thushighlighting the requirement for accurate recording and systematic research.

The interest in the conservation of biodiversity among both respondent groups reflected 312 similar attitudes across Europe (Thornton, 2009; European Commission, 2015) and was 313 coupled with a concern for the native Irish hare. However, this did not translate into support 314 for lethal culling amongst respondents who owned land, presenting a potential impediment to 315 the implementation of management programmes (Susskind & Cruickshank, 1987, cited in 316 Decker *et al.*, 1996). Any eradication attempt that cannot access the full range of the species 317 318 is unlikely to succeed and, hence, should be sensitive to the need for considered engagement of landowners. Eradication is not the only option available to decision-makers. The current 319 invasive range, while expanding, is still relatively small (Caravaggi et al., 2015) and is 320 321 constrained by Lough Neagh to the east and the unsuitable heather moorland habitat of the Sperrin mountain range to the west which present potential barriers to longitudinal dispersal. 322 Hence, the European hare could be effectively contained within its current invasive range by 323 lethal control along the northern and southern range edge margins. However, the zone of 324 sympatry between the European and Irish hares is extensive; issues of species discrimination 325 in-situ would remain and dispersing Irish-like first-generation (F1) hybrids would continue to 326 threaten the genetic integrity of the Irish hare. Habitat management aimed at improving the 327 landscape for native hares, to the detriment of the invader, represents a possible alternative to 328 329 lethal management but is unlikely to be effective in controlling the invasive population given their ecological similarity to the native species (Reid & Montgomery, 2007; Caravaggi et al., 330 2015). 331

In conclusion, the fundamental interest in natural heritage, conservation, and the welfare of the Irish hare demonstrated by the majority of respondents suggests that an effective, acceptable means of control and/or eradication of the European hare in Ireland may be

possible. Moreover, a small number of interrelated factors may be relevant in determining 335 how an individual responds to future invasive species management proposals. CAI members, 336 many of whom hunt and shoot (i.e. own a gun licence), represent a huge potential resource 337 with around 3,500 local members (Lyall Plant, pers comm), approximately half of whom 338 (52% of affiliated respondents) may be willing to participate in a voluntary coordinated 339 control or eradication programme In addition, support from organisations such as CAI may 340 help persuade other groups with similar interests and goals - for example, the British 341 Association for Shooting and Conservation (BASC) or the Game and Wildlife Conservation 342 Trust (GWCT) or local private gun clubs (e.g. the Megargy and District Game and 343 Conservation Society) - to become actively engaged. The level of support for lethal 344 management among non-members and the reluctance of landowners to permit access to their 345 346 land present immediate obstacles. Hence, the first steps towards making any management process a reality involve outreach and engagement with stakeholders. This study provides 347 vital data which will be of considerable value to decision-makers in Northern Ireland and is 348 an example for similar initiatives elsewhere within the global invasive range of European 349 hare or other invasive species. 350

352 Acknowledgements

We are grateful to Declan Looney who acted as NIEA Client Officer and commented on the questionnaire design and a draft of this manuscript, Lyall Plant and Countryside Alliance Ireland for their willingness to participate in this study, supporting questionnaire distribution, and all those who responded to the survey. We thank the editor and reviewers, whose comments and suggestions were instructive in improving this manuscript. None of the views expressed in this paper are the policy or views of either the Department of Agriculture, Environment and Rural Affairs (DAERA) or Countryside Alliance Ireland.

361Funding: This project was funded by the Natural Heritage Research Partnership (NHRP)362between then Northern Ireland Environment Agency (NIEA) and Quercus, Queen's363UniversityBelfast(QUB).

Table 1. The number of responses, and the percentage of those responses which were positive, to each question in a survey of attitudes to lethal management of invasive European hares in Northern Ireland. Where questions are accompanied by an asterisk (13c), all responses were positive, thus percentages were calculated relative to the parent question (13b). Total positive responses to 13c for both groups exceeded the number of positive responses for 13b within which they are nested as many respondents selected more than one option. Conversely, a number of non-members did not select an option in 13c. See Supplementary Information 1 for full question text.

		Countryside Alliance Ireland members		Non- me	mbers
	Question	Number of responses	Yes (%)	Number of responses	Yes (%)
1	Landowner/user	140	51	202	77
2	Farmer	140	24	202	42
3	Concerned with conservation of biodiversity	134	88	191	82

19	Allow a cull on their land (no direct involvement)	70	47	130	41
20	Support Governmental decision to cull European hares	139	65	183	54

Table 2. Relative importance of explanatory variables in the best approximating model explaining support of lethal management of the European hare in Northern Ireland. $\Sigma \omega_i = \text{sum of Akaike weights}$; *p* values are denoted as * *p*<0.05, ** *p*<0.01, and *** *p*<0.001. Question numbers are given in parentheses (see Supplementary Information 1 for full text). For all variables including in model averaging, see SI 2.

Question	$\Sigma \omega_i$	Effect size ($\beta \pm SE$)
Would petition government (Q14)	1.00	0.57 ± 0.05 ***
Support management (Q12)	1.00	0.18 ± 0.06 **
Hunt (Q17)	1.00	0.16 ± 0.05 **
Aware of two hare species (Q8)	0.57	$\textbf{-0.07} \hspace{0.1in} \pm \hspace{0.1in} 0.05$
Conservation concern (Q3)	0.55	-0.09 ± 0.06

Fig. 1. a) The distribution of settlements throughout Northern Ireland within which randomly-selected residents were surveyed using questionnaires. **b)** Locations of European hare records (n = 106) reported by questionnaire respondents, scaled according to the numbers of respondents or who claimed to see European hares. The dashed-line polygons denote the invasive European hare's core range (inner 50% Minimum Convex Polygon or MCP), peripheral range (outer 100% MCP), and a small remnant population (5 individuals identified in 2012-13; unpublished data from surveys published as Caravaggi *et al.*, 2015) in West Tyrone.

Fig. 2. The distribution of questionnaires to two responder groups across three geographic zones describing European hare occurrence in Northern Ireland. CAI = Countryside Alliance Ireland. n_i = number of questionnaires per group. For details on how zones were delineated, see Caravaggi *et al.* (2015).

Fig. 3. Public perceptions of hare population temporal trends over (a) the last 5 years (2009 – 2014) and (b) the last 50 years (1964 - 2014) throughout Northern Ireland for both the native Irish and invasive European hares. The percentage of respondents answering 'decreasing' (black), 'no change' (grey) and 'increasing' (white) within the three zones of invasion: i) native species allopatry, ii) the invasive species' peripheral range and iii) the invader's core range are presented for Countryside Alliance Ireland members (CAI) and non-members (NM). Horizontal black lines represent the mean of those answering 'decreasing'.

Fig. 4. Percentage \pm 95% confidence limits of Countryside Alliance Ireland members (CAI; grey) and nonmembers (NM; white) who (a) support lethal culling of the invasive European hare in Northern Ireland and (b) split between each zone of invasion. Superscript letters above the bars represent significant differences (p<0.05) between groups using Tukey *post-hoc* tests: A > a; B > b.

Fig. 5. Percentage \pm 95% confidence limits of respondents who own or rent land who would allow a survey to be carried out on their land (grey), and would allow lethal management of the European hare to be carried out on their land (white) if the species was found to be present.

Questionnaire on hares in Northern Ireland

Ref	ference number:	Date:		_		
	Contact details (<u>OPTIONAL</u>)					
	Name:					
	Address:					
	Telephone number:	Email:				
1.	a) Do you own or rent land for agriculture, forestry or so b) Specify which:	ome other purpose?	Yes Agricultur Forestry Other, ple	□ re ase spec	No :ify	
	c) Approximately how much land do you own/rent?		ha or	<u>.</u> acres		
2.	a) Are you an active farmer? b) If yes, what is the main focus of your farm?		Yes Beef cattle Dairy catt Sheep Arable Mixed	□ e le	No	
3.	Are you concerned with the conservation of biodiversity	?	Yes No			
4.	a) Have you seen hares in Northern Ireland? b) If yes, when was your most recent sighting?		Yes 0 – 6 mont 6 months – 1 – 2 years 2 + years a	□ ths ago - 1 year s ago ago	No ago	
5.	Do you consider hares to be agricultural pests?		Yes		No	
6.	What is your impression of hare numbers during your lif (up to last 50 years)?	îetime	No change Increasing Decreasing	g g		
7.	What is your impression of hare numbers over the last 5	years?	No change Increasing Decreasing	e g		

Please read this information before completing the rest of the questionnaire

The native Irish hare (*Lepus timidus hibernicus*) is one of the characteristic animals of Ireland having been isolated here for at least 25,000 years. Irish hare populations have undergone a population decline throughout the 20th century. As a result, it is a high priority for conservation action and is subject to national and international legislation which aim to protect native biodiversity.

The invasive European brown hare (*Lepus europaeus*), also known locally as the 'English' or 'thrush' hare, is not native to Ireland having been introduced in the 1800s for field sports. They are typically found on flatter, drier land, particularly areas with some arable agriculture (i.e. crops). In Northern Ireland, they are found in mid-Ulster and west Tyrone (see map).

Features: Sandy brown Mottled coat Angular head Black tail Ears longer than head Black tips to ears very distinct

European hares were introduced to Sweden in the 1800s. Being bigger than the native mountain hares, they were able to out-compete the natives for food and mates. The mountain hare is now locally extinction throughout much of southern Sweden.

The Irish hare is bigger and more adaptable than its other mountain hare relatives so may provide stiffer opposition to invasion by European hares. However, studies have shown than the range of the European hare in mid-Ulster is expanding and that some areas show a considerable amount of hybridisation (offspring produced from both species interbreeding).

Native Irish hare

Russet reddy brown Smooth colouration Rounded head White tail Ears same length as head Black tips to ears not distinct

Map showing the distribution of European hares in Northern Ireland.

The European hare presents a significant threat to the security of the Irish hare. Europeanlevel legislation requires the UK and Ireland to address issues of invasive species and some have called for the invader to be controlled or eradicated in Northern Ireland.

8.	Were you <u>previously</u> aware that there were two kinds of hare in Northern Ireland?	Yes		No	
9.	a) To the best of your knowledge, have you ever seen a European brown hare in Northern Ireland?	Yes		No	
	b) If yes, where (nearest town)?		<u>-</u> .		
10.	a) If you are a landowner or manager, have you ever seen European hares on your land?b) If yes, where (nearest town)?	Yes		No	
	c) If yes, when was your most recent sighting?	0 – 6 months ago 6 month- 1 year ago 1 – 2 years ago 2 + years ago			
11.	Do you <i>personally</i> consider the threat posed by the European hare to the native Irish hare to be important?	Yes		No	
12.	Would you support management aimed at mitigating the impact of the European hare?	Yes		No	
13.	Do you support the notion of either of the following:				
	a) Non-lethal habitat management to benefit the Irish hare?	Yes		No	
	b) Lethal culling to control or eradicate the European hare	Yes		No	
	c) If so, which method would you support (tick all that apply):	Shooting Netting Trapping			
14.	Would you actively support a cull by signing a petition to lobby Government for action? (note that you will not be asked to actually do so – this is only <i>hypothetical</i>)	Yes		No	
15.	a) If you are a landowner or manager would you allow your land to be surveyed for European hares?	Yes		No	
	b) If yes, and European hares were found to be present would you permit them to be culled by (planned and responsible) shooting?	Yes		No	
16.	Are you a member of a conservation organisation, specifically <u>not</u> affiliated with shooting e.g. the Ulster Wildlife Trust?	Yes		No	

17.	a) Do you hunt/shoot?b) If yes, what do you hunt/shoot?	Yes Game birds Rabbits Wildfowl Fishing/ang Other (please spec	□ s ling ify belo	No ww)	
18.	Would you actively support a cull by participating in coordinated shooting of European hares (under direction) either on your own land or land on which you have permission?	Yes		No	
19.	If you would not actively participate in coordinated shooting of European hare and you are a landowner/manager, would you be willing to allow a cull on your land?	Yes		No	
20.	If the government planned and/or supported a cull of European hares, would you support this decision?	Yes		No

Model averaging

Variance inflation factors (VIF values) between pairs of variables were ≤ 3 (Zuur et al., 2009) indicating that all could be fitted simultaneously as independent explanatory variables, with the exception of Q20 (VIF = 3.1). Data were standardized to have a $\bar{x} = 0$ and $\sigma = 1$ prior to analysis, thus permitting the direct comparison of regression coefficients. All possible model permutations were created and ranked according to their Akaike Information Criterion (AIC) values. The Akaike weight (ω_i) of each model within the top set of *N* models (i.e. $\Delta AIC \leq 2$; Burnham & Anderson, 2002) was calculated. The relative importance of each variable within the top set of models was ascertained by calculating $\Sigma \omega_i$ (McAlpine *et al.*, 2006), where the higher the value (between 0 and 1), the more important the variable. The effect size (standardised β coefficient \pm SE) of each variable across the top set of models was determined via multimodel inference and model averaging (Burnham & Anderson, 2002; Fig. S2.1).

Selected additional comments provided by questionnaire respondents. Some comments have been edited for brevity.

Countryside Alliance Ireland members:

Reasons for hare declines:

- "Over the last 60 years European and Irish hares have both become scarce in this area. Their decrease is a result of big changes in agricultural practise heavier grazing and early silage cutting."
- "Hare are no longer common in my area. Too many predators and early silage cutting."
- "The threat to the Irish hare comes from slurry sprayed on land and domestic cats kills all the young."
- "The reason for the decline in hare population is the whole country is overrun with vermin: mink, buzzards, pine marten, stoats, rats, magpies, crows, buzzards, foxes."

Reasons for increases hare numbers:

• "On land controlled for shooting, making it more wildlife friendly, we have seen hare numbers increase slightly."

Against a cull:

- "I do not believe this to be true. The European hare is not a threat. They favour different types of ground."
- "Government culls tend to be very expensive. Would rather see money spent on habitat improvement and conservation of Irish hare / containment of European."
- "There needs to be a law passed to ban lamping at night-time... If you are going to cull the European hare, are you going to replace with the Irish hare?"
- "There is a hunt club in my area and I would not like to shoot hares as it would harm the huntmen's sport."

Concerns regarding species identification:

- "Concerned that the wrong hare would be shot. Identification would have to be accurate."
- "I would be very afraid that when word of a cull became common knowledge, it would result in the death of some Irish hares."
- "I would fully support an action plan to promote and conserve native Irish hare numbers but I feel that shooting is the wrong answer. It can be difficult to differentiate between the Irish hare and European hare unless up close and with practise."

Non-members:

Reasons for hare declines:

- "50 years ago we had a large number of European brown & Irish hares. Over the last ten years, hares have disappeared totally from our area. I would blame this on the increase of foxes and buzzards."
- "Cut down birds of prey and foxes to get the population of hares to rise."
- "I do not think the European hare is a threat to Irish hares. I believe a bigger threat is foxes and crows."

Reactions to information sheet:

- "I would like to know more about a cull before I would be comfortable with it. Your article was very informative."
- "I was unaware of the two species of hare until the survey."

Concerns regarding culls:

- "I would like to see the native hare preserved but would need much greater detail and evidence before actively supporting a cull."
- "If there was strong evidence of the European hare posing a significantly negative effect on the Irish hare then we would re-think my position on a cull."
- "I am sensitive about hurting animals, but I do understand the need to save the species."
- "I am not convinced European hares pose a risk to the native species. I find hare populations to be low on my farm. I find culling a cruel method of control, shooting or otherwise, as it impacts on offspring which may inhabit forms and can starve after the death of the adult."

Regarding (invasive) species management:

- "Would you cull all the other invasive species? Mink, grey squirrel, ferret, etc."
- "If the non-native hares can be trapped, why kill them? There must be other parts of Europe where they are in decline. Why not work with other conservation groups to reintroduce them? Cull shows limited and insular thinking."
- "In my opinion it is not hares that are the problem, it is rabbits."
- "Better any hare than none at all."
- "Farmers should be doing better management of their lands for the betterment of the Irish hare."
