Abstract

The aim of this work was to investigate the potential of pegylated poly(anhydride) nanoparticles to enhance the oral bioavailability of docetaxel (DTX). Nanoparticles were prepared after the incubation between the copolymer of methyl vinyl ether and maleic anhydride (Gantrez[®] AN), poly(ethylene glycol) (PEG2000 or PEG6000) and docetaxel (DTX). The oral administration of a single dose of pegylated nanoparticles to mice provided sustained and prolonged therapeutic plasma levels of docetaxel for up 48-72 h. In addition, the relative oral bioavailability of docetaxel was around 32%. The organ distribution studies revealed that docetaxel underwent a similar distribution when orally administered encapsulated in nanoparticles as when intravenously as Taxotere[®]. This observation, with the fact that the clearance of docetaxel when loaded into the oral pegylated nanoparticles was found to be similar to that of intravenous formulation, suggests that docetaxel would be released at the epithelium surface and then absorbed to the circulation.

Key words: docetaxel, nanoparticles, pegylated, oral delivery; bioavailability

1 1. Introduction

2 Docetaxel (DTX) is a semisynthetic taxoid, analogue of paclitaxel, derived from the European 3 yew tree (Taxus bacata sp.) and it is one of the most effective drugs in chemotherapy. It has proven to be useful against several types of cancers such as breast, ovarian, prostate, head 4 and neck, gastric and non-small lung cancers [de Weger et al., 2014; Nieuweboer et al., 5 6 2015]. The mechanism of action of DTX, like other taxanes, is based on the stabilization of 7 the microtubule dynamics and thereby disruption of the cell cycle [Nieuweboer et al., 2015]. 8 This is due to its stronger binding capability to tubulin, docetaxel shows about 2 to 4 times more cytotoxicity effect on tumor cells than that of paclitaxel [Jones, 2006]. Docetaxel 9 (Taxotere[®] and generics) is formulated as a concentrated aqueous solution containing 10 polysorbate 80 (Tween[®] 80). The presence of this non-ionic surfactant has been related with 11 12 severe side effects in some patients, including anaphylactic hipersensitivity reactions and cumulative fluid retention [Tang et al., 2016]. In order to minimize allergic reactions, patients 13 require premedication with antihistamines (H₂) and corticosteroids [Kang et al., 2017]. 14 Therefore, investigation of alternative intravenous formulations of docetaxel is underway, 15 and several approaches based on conjugates with albumin [Esmaeili et al., 2009], 16 17 nanoparticles [Cho et al., 2011; Hwang et al., 2008], liposomes [Deeken et al., 2013] and micelles [Dou et al., 2014] have been proposed. 18

Another possibility for docetaxel administration would be the use of the oral route. An important argument for docetaxel oral delivery is that this route of administration facilitates the implementation of chronic regimens and other dosing schedules such as metronomic therapies. This is particularly interesting for cell cycle specific agents and compounds with a predominant cytostatic effect (e.g. docetaxel) [Jiang et al., 2010; Wu et al., 2011]. Moreover,

oral chemotherapy can provide an easy way for the patients to take the drug by themselves
at home, which will reduce their medical expenses and improve their quality of life.

Nevertheless, docetaxel has a poor oral bioavailability of about 8% in humans [Malingré et 26 al., 2011] and less than 4% in rodents [Bardelmeijer et al., 2002]. The main reasons for this 27 low and variable oral bioavailability of DTX are related to a high lipophilicity and a low 28 29 permeability within the gut. In fact, docetaxel has poor aqueous solubility (4.93 µg/ml) and 30 upon oral administration, intestinal uptake is seriously hampered by drug efflux through 31 intestinal P-glycoprotein (P-gp) and systemic exposure is further limited by drug metabolism via cytochrome P450 (CYP) 3A [Kuppens et al., 2005; Malingré et al., 2001]. One of the most 32 popular strategies to boost the oral bioavailability of docetaxel is the combination of an oral 33 formulation of the taxane with inhibitors of both P-gp and CYP3A4. Therefore, different 34 35 preclinical and clinical studies have demonstrated the validity of this idea based on the coadministration of the anticancer drug with cyclosporine A [Chiou et al., 2002] or ritonavir 36 and elacridar [Hendrikx et al., 2014]. However, the use of drugs that inhibit these enzymes 37 and transporters involves potential risks. In order to minimize these side effects other 38 inhibitors such as curcumin [Yan et al., 2010] or flavonoids [Yang et al., 2011] have been 39 40 proposed.

Another approach may be the use of pegylated poly(anhydride) nanoparticles. These nanoparticles based on the copolymer of methyl vinyl ether and maleic anhydride (Gantrez[®] AN), have demonstrated a good ability to improve the oral bioavailability of paclitaxel (up to 10 times, compared with "naked" nanoparticles) [Zabaleta et al., 2012; Calleja et al., 2014]. These results may be explained by the capability of PEG coatings to confer a high stability in digestive fluids minimizing the interaction of these nanoparticles with lumen contents [Tobio et al., 2000]. Similarly, the coating of nanoparticles with poly(ethylene glycol)s (PEGs) would

48 yield nanoparticles with slippery properties that facilitate the passage of these carriers 49 through the mucus layer which is covering and protecting the intestinal epithelium 50 [Yoncheva et al., 2005; Inchaurraga et al., 2015]. In addition, PEGs possess the disturbing 51 capability on the effect of both the intestinal P-glycoprotein efflux pump [Hugger et al., 52 2002] and the cytochrome P450 [Johnson et al., 2002]. These activities may be of interest to 53 promote the oral absorption of docetaxel.

Therefore, the aim of this work was the evaluation of the capability of pegylated poly(anhydride) nanoparticles as oral carriers for docetaxel. For this purpose, pegylated nanoparticles containing DTX were optimised and orally administered to Balb/c mice in order to study the pharmacokinetics and tissue distribution of this anticancer drug.

58

59 2. Materials and Methods

60 **2.1. Materials**

Docetaxel (USP 30, grade 99.0%) and paclitaxel (USP 28, grade >99.5%) were supplied by 61 21CECpharm (London, UK). Poly(methyl vinyl ether-co-maleic anhydride) or poly(anhydride) 62 (PMV/MA) [Gantrez[®] AN 119; MW 200,000; density: 1.03 g/mL] was purchased from 63 64 International Specialty Products ISP/Ahsland Inc. (KY, USA). Taxotere® from Sanofi-Aventis was provided by the Pharmacy Service of University Clinic of Navarra (Pamplona, Spain). 65 66 Phosphate buffered saline (PBS), pancreatin and glycine were obtained from Sigma Aldrich (MO, USA). Poly(ethylene glycol) with MW of 2000 and 6000 Da (PEG2000 and PEG6000, 67 respectively) and disodium edetate (EDTA) were provided by Fluka (Buchs, Switzerland). 68 69 Pepsin, acetone, ethanol, t-buthylmethylether and acetonitrile were obtained from Merck (Darmstadt, Germany). Polysorbate 80 (Tween® 80) was supplied by Panreac (Barcelona, 70 71 Spain). Deionised reagent water (18.2 M Ω resistivity) was prepared by a water purification system (Wasserlab, Pamplona, Spain). The anaesthetic isoflurane (Isoflo[®]) was from
laboratories Esteve (Barcelona, Spain). All others reagents and chemicals used were of
analytical grade.

75 **2.2.** Preparation of poly(anhydride)nanoparticles

Docetaxel (DTX) was encapsulated in either conventional [Arbos et al., 2003] or pegylated poly(anhydride) nanoparticles. Pegylated nanoparticles with either PEG2000 or PEG6000 were prepared following the method published by Zabaleta et al. (2012) with minor modifications.

80 2.2.1. Docetaxel-loaded pegylated poly(anhydride) nanoparticles

Briefly, either PEG2000 or PEG6000 (12.5 mg) were firstly dispersed in 3 mL acetone and 81 added to a solution of acetone containing 100 mg Gantrez[®] AN. The resulting mixture was 82 83 maintained under magnetic agitation. On the other hand, docetaxel was dissolved in 0.5 mL acetone and added to the polymers mixture. Then, the organic phase containing DTX, 84 PVM/MA and PEG was incubated for a period of 1 hour under magnetic stirring at room 85 temperature. Afterwards, nanoparticles were formed by the addition of 20 mL of a 86 hydroalcoholic solution (50% ethanol) containing glycine (0.5% w/v) and disodium edetate 87 88 (0.18% w/v). The mixture was maintained under agitation for 10 minutes. The organic solvents were eliminated by evaporation under reduced pressure (Büchi Rotavapor® R-144; 89 90 Büchi, Postfach, Switzerland) and the nanoparticle suspensions were purified by tangential 91 filtration in Vivaspin tubes (Vivascience Sartorius, Hannover, Germany; MW cut off: 300,000) 92 at 4,000 xg for 15 min. The pellets were resuspended in water and the purification step was 93 repeated again. Finally, the formulations were frozen and freeze-dried (Genesis 12 EL Freeze 94 Dryer; Virtis, PA, USA) using sucrose (5%) as cryoprotector. The resulting nanoparticles were 95 identified as DTX-NP2 (docetaxel-loaded pegylated nanoparticles with PEG2000) and DTX-

- 96 NP6 (docetaxel-loaded pegylated nanoparticles with PEG6000).
- Empty pegylated nanoparticles (NP2 and NP6) were prepared in the same way as described
 above but in absence of docetaxel and used as controls.
- 99 2.2.2. Docetaxel-loaded poly(anhydride) nanoparticles

Ten mg of docetaxel were incubated with 100 mg Gantrez[®] AN under magnetic stirring at room temperature for 1 hour in 5 mL acetone. Then, nanoparticles were formed by the addition of 20 mL of a mixture of ethanol and water (1:1 by vol.) containing glycine (0.5% w/v) and disodium edetate (0.18% w/v). The organic solvents were eliminated by evaporation under reduced pressure and the resulting nanoparticles were purified and freeze-dried as described above.

Empty poly(anhydride) nanoparticles (NP) were prepared in the same way but in the absence of docetaxel. For identification, the following abbreviations were used: NP, poly(anhydride) nanoparticles; DTX-NP, docetaxel-loaded poly(anhydride) nanoparticles.

- 109 2.3. Characterization of nanoparticles
- 110 **2.3.1.** Physico-chemical characterization

111 The mean hydrodynamic diameter of the nanoparticles and their zeta potential were 112 determined by photon correlation spectroscopy (PCS) and electrophoretic laser Doppler anemometry, respectively, using a Zetamaster analyzer system (Malvern Instruments Ltd., 113 114 Worcestershire, UK). The diameter of the nanoparticles was determined after dispersion in ultrapure water (1:10) and measured at 25°C by dynamic light scattering angle of 90°C. The 115 zeta potential was determined as follows: 200 µL of the samples were diluted in 2 mL of a 116 117 0.1 mM KCl solution. The yield of the process was calculated by gravimetry as described 118 previously [Arbos et al., 2003].

119 The morphological examination of the nanoparticles was carried out by field emission scanning electron microscopy (FESEM) and by energy-filtered transmission electron 120 121 microscopy (EFTEM). For FESEM analysis, nanoparticles were washed before imaging by centrifugation to remove the cryoprotector. For this purpose, a small amount of the freeze-122 dried nanoparticles was resuspended in ultrapure water and centrifuged at 27,000xg for 10 123 124 min. Then, the supernatants were rejected and the obtained pellets were mounted on 125 copper grids. FESEM was performed using a Zeiss ultra Plus electron microscopy (Carl Zeiss SMT, Oberdochen, Germany) operating between 1 a 2 Kv from 3 mm distance. 126

EFTEM was performed in a Zeiss Libra 120 (Carl Zeiss SMT, Oberkochen, Germany) operating at 80 kv. For this purpose, 20 μL of a suspension of nanoparticles were deposited onto copper grids for 1 min and excess suspension was blotted off using filter paper. Finally, samples were stained with phosphotungstic acid at 2% for 15 sec. The excess of this solution was blotted off using filter paper and grids were air dried before observation. Images were adquired using a 2k bottom-mount SlowScanCCD with YAG scintillator high-resolution camera (TRS-system, Moorenweis, Germany).

134 **2.3.2.** X-ray photoelectron spectroscopy (XPS)

135 Surface chemical composition of the nanoparticles was studied by X-ray photoelectron spectroscopy (XPS) in a SPECS SAGE HR 100 (SPECS, Berlin, Germany) spectrometer equipped 136 137 with a Mg Kα (1253.6 eV) non-monochromatic source operated at 250 W. The take-off angle was fixed at 90° and the analyses were conducted at a pressure of $\sim 10^8$ mbar. The pass 138 energy was set at 30 and 15 eV for the general survey and the high resolution scans, 139 140 respectively. The step size was 0.5 eV for the survey spectra and 0.1 for the high-resolution spectra, respectively. Charge compensation was achieved with an electron flood gun in the 141 analysis chamber. The XPS data were processed with casaXPS V2.3.15 software 142

(Casa Software Ltd., Teignmouth, UK). Spectra were calibrated with the C-C peak position fixed at 285.0 eV [Moulder et al., 1992] after a Shirley background subtraction. The fitting procedure was done constraining the peak widths (same width for all peaks on each element) while the peak positions and areas were set free.

147 **2.3.3.** Quantification of the amounts of PEG associated with nanoparticles

148 The amount of PEG associated to the nanoparticles was determined by HPLC coupled to an 149 evaporative light scattering detector (ELSD) [Inchaurraga et al., 2015], with minor 150 modifications. Briefly, analysis was carried out in a model 1100 series Liquid Chromatography, Agilent (Waldbronn, Germany) coupled to an ELSD 2000 Alltech apparatus 151 (Illinois, USA). Separation was carried out on a PL Aquagel-OH column (300 mm x 7.5 mm; 152 153 particle size 5 μ m) (Agilent, Wokingham, UK), in a gradient elution with methanol-water as 154 mobile phase at a flow rate of 1 mL/min. ELSD conditions were set as follows: drift tube temperature was maintained at 110 °C, nitrogen flow was set at 3 L/min and the gain was 1. 155 For the quantification of PEG2000, ELSD conditions were modified as follows in order to 156 achieve maximum sensitivity: the drift tube temperature was set at 90°C, the nitrogen flow 157 158 was maintained at 3.2 L/min and the gain was set to 2.

For analysis, supernatants collected during the purification step of the preparative process were centrifuged at 17,000 rpm for 20 min at 4°C. Then, aliquots of the supernatants (20 μL) were injected onto the HPLC column. The amount of PEG associated to nanoparticles was calculated as the difference between the initially added amount of PEG to the solution of the polymer in acetone and the amount of PEG recovered in the supernatants. Each sample was assayed in triplicate and the results were expressed as the amount of poly(ethylene glycol) per mg of nanoparticle.

166 **2.3.4.** Evaluation of the average PEG chain density and conformation state

The PEG surface density (d_{PEG}), the average distance between two neighbouring PEG chains (D) and the Flory Radius were calculated following the procedure described previously [Inchaurraga et al., 2015]. Then, the conformation state of PEG on the surface of nanoparticles was calculated by comparing D and RF. In any case, it was assumed that all the nanoparticles were spherical and displayed the same size (the mean size calculated by PCS). Similarly, it was also assumed that the associated PEG (as calculated by HPLC) was localized on the surface of the nanoparticles.

174 **2.3.5.** Docetaxel content in nanoparticles

The amount of docetaxel loaded in the nanoparticles was quantified by HPLC-UV. The 175 analytical apparatus was an Agilent model 1200 series LC coupled to a diode-array detector 176 (Agilent) set at 228 nm. The chromatographic system was equipped with a reversed-phase 177 178 150 mm x 3 mm C18 Phenomenex Gemini column (particle size 5 μ m; Phenomenex, CA, USA) and protected by a 0.5 µm precolumn filter. The mobile phase, pumped at 0.5 mL/min, 179 was a mixture of phosphate buffer (0.01 M; pH 2.1) and acetonitrile (50:50 v/v). The column 180 was placed at 30°C and the injection volume was 100 µL. Paclitaxel (PTX) was used as 181 182 internal standard. Under these experimental conditions the run time was 16 min and 183 paclitaxel and docetaxel eluted at 6.8 and 8.2 min, respectively. For the calculations, the standard curve of docetaxel was designed over the range between 1.25 and 320 µg/mL 184 (r²>0.999). The limit of quantification was calculated as 60 ng/mL with a relative standard 185 deviation of 4.5%. 186

For analysis, nanoparticles were digested with acetonitrile (1:8 volume ratio). Samples were transferred into auto-sampler vials, capped and placed in the HPLC auto-sampler. Each sample was assayed in triplicate and the results were expressed as the amount of docetaxel (μg) per mg of nanoparticles.

191 The encapsulation efficiency (E.E) was calculated as follows:

192

E.E. (%) =
$$(Q_{associated}/Q_{initial}) \times 100$$
 (Eq.1)

Where Q_{initial} is the initial amount of DTX added and Q_{associated} is the amount of entrapped DTX

in the nanoparticles, which is calculated by HPLC.

196 2.4. In vitro release study

197 Release experiments were conducted, under sink conditions, at 37°C using simulated gastric 198 (SGF; pH 1.2; pepsin 0.32% w/v) and intestinal (SIF; pH 6.8; pancreatin 1% w/v) fluids 199 containing 0.5% of polysorbate 80 (Tween[®] 80) as solubilising agent for docetaxel. The 200 studies were performed under agitation in a Vortemp 56^{TM} Shaking incubator (Labnet 201 International Inc., NJ, USA) after the dispersion of the nanoparticles in the appropriate 202 medium.

For each time point, 50 µg docetaxel formulated in nanoparticles were resuspended in 2 mL 203 204 of the corresponding simulated fluid. The concentration of the nanoparticles in the release medium was adjusted in order to assess sink conditions for docetaxel. The different 205 formulations were kept in the SGF for 2 hours and for 14 hours in SIF. At different time 206 points, sample tubes were collected and centrifuged at 27,000xg for 20 minutes. Finally, 207 208 samples were filtered and the amount of docetaxel released from the formulations was quantified by HPLC (calibration curves of free docetaxel in supernatants obtained from SGF 209 and SIF, r²>0.999). Release profiles were expressed in terms of cumulative release 210 211 percentage, and plotted versus time.

212 2.4.1. Analysis of release data

Data obtained from the *in vitro* release experiments were treated by various conventional mathematical models to determine the release mechanism of the drug from the nanoparticles. Based on the highest regression values (r^2) for correlation coefficients for

formulations, the best-fit model was decided. For this purpose, the following models were used: the Korsmeyer-Peppas equation (Eq.2), the Higuchi equation (Eq.3), and zero-order equation (Eq.4).

The Korsmeyer-Peppas model exponentially relates drug release with the elapsed time[Ritger and Peppas, 1987]:

221

 $M_t/M_{\infty} = K_{KP} \times t^n$ (Eq.2)

222

In which M_t/M_{∞} is the fraction of released drug at time t, K_{KP} is a constant incorporating the structural and geometric characteristics of the matrix, and n is the release exponent indicating the drug release mechanism. If "n" value is around 0.5 (the exact value depends on the geometry), the mechanism is Case I (Fickian) diffusion. A value between 0.5 and 0.89 indicates anomalous (non-Fickian) diffusion and a value of 0.89 and above indicates a Case II Transport.

229 When the release mechanism is mainly based on a Fickian diffusion, a dimensionless 230 expression of the Higuchi model can be applied [Costa and Sousa, 2011]:

231 $M_t/M_{\infty} = K_H \times t^{1/2}$ (Eq.3)

232

233 Where M_t/M_{∞} is the fraction of released drug at time t, and K_H is the Higuchi constant.

Finally, the following zero-order kinetic model was also used. This model is used for systems where the matrix releases the same amount of drug by unit of time:

236 $Q_t = Q_0 + K_{ZO} \times t$ (Eq.4)

237

238 Where Q_t is the amount of drug dissolved in time t and Q_0 is the initial amount of drug in the

solution (most times, $Q_0 = 0$) and K_{ZO} is the zero-order release constant.

The analysis was applied to the release study of docetaxel performed under simulated intestinal fluid, until the 60-80% of drug released. All data processing was performed using Origin 8.0 software (OriginLab Corporation, MA, USA).

243 2.5. Pharmacokinetic studies

Pharmacokinetic studies were carried out in Balb/c female mice (average weight 19-22 g) 244 245 obtained from Harlan (Santiga, Spain). Studies were approved by the Ethical Committee for Animal Experimentation of the University of Navarra (protocol number E21-12) in 246 247 accordance with the European legislation on animal experiments (86/609/EU). Before the experiment, animals were adaptively fed for 1 week with free access to food and drinking 248 water (22 ± 2°C; 12-h light and 12-h dark cycles; relative humidity 55 ± 10%). Previous to the 249 250 oral administration of the formulations, animals were fasted overnight to avoid the 251 interference with the absorption, allowing free access to water.

For the pharmacokinetic study, the animals were randomly divided into five groups. The 252 experimental groups were as follows: (a) DTX-NP2, (b) DTX-NP6 and (c) DTX-NP. As controls, 253 one group of animals received Taxotere[®] intravenously and another group was treated with 254 255 the commercial formulation orally. Each animal received the equivalent amount of docetaxel 256 to a dose of 30 mg/kg body weight (bw) either orally with a blunt needle via the esophagus into the stomach or intravenously via tail vein as a slow infusion. All the formulations were 257 258 administered dispersed or dissolved in either purified water (oral) or sterile saline 259 (intravenous). All animals were observed for their general condition and clinical signs.

At established times after administration, blood was obtained from 4 animals in each group. EDTA was used as an anticoagulant agent. Blood volume was recovered intraperitoneally with an equal volume of normal saline solution preheated at body temperature. Samples

were immediately placed on ice and centrifuged at 2,500xg for 10 minutes. Plasma was separated into clean tubes and kept frozen at -80°C until HPLC analysis.

265 **2.5.1.** Determination of DTX plasma concentration by HPLC-UV

The amount of docetaxel was determined in plasma by HPLC-UV as described above. The 266 267 extraction method was adapted from Zhao et al. (2010). Calibration curves were used for the 268 conversion of the DTX/PTX chromatographic area to the concentration. Calibrator and 269 quality control samples were prepared by adding appropriate volumes of standard docetaxel 270 in ethanol to drug free plasma. Calibration curves were designed over the range between 100 and 3200 ng/mL (r^2 >0.999). An aliquot (200 µL) of plasma was mixed with 25 µL of 271 internal standard solution (paclitaxel, 10 µg/mL in ethanol). After vortex mixing, liquid–liquid 272 extraction was accomplished by adding 3 mL of tert-buthylmethylether following vortex 273 274 gentle agitation (10 min). The mixture was centrifuged for 10 min at 2,500xq, and then, the organic layer was transferred to a clean tube and evaporated to dryness (Thermo Savant, 275 Barcelona, Spain). The residue was then dissolved in 125 µL of reconstitution solution 276 (acetonitrile-phosphate buffer; 0.01 M; pH 2.1; 50:50 v/v) and transferred to auto-sampler 277 278 vials, capped and placed in the HPLC auto-sampler. A hundred microlitre-aliquot of each 279 sample was injected onto the HPLC column.

Under these experimental conditions the UV detection of docetaxel was performed at 228 nm and the run time was 16 min. The limit of quantification was calculated to be 140 ng/mL with a relative standard deviation of 5.3%. Accuracy values during the same day (intraday assay) at low, medium and high concentrations of docetaxel were always within the acceptable limits (less than 5%) at all concentrations tested.

285 **2.5.2.** Pharmacokinetic data analysis

286 The pharmacokinetic analysis of plasma concentration plotted against time data, obtained

287 from the administration of the different docetaxel formulations, was performed based on a non-compartmental model using WinNonlin 5.2 software (Pharsight Corporation, MO, USA). 288 The following parameters were estimated: maximal plasmatic concentration (C_{max}), time in 289 which the maximum concentration is reached (T_{max}), area under the concentration-time 290 curve from time 0 to t h (AUC), mean residence time (MRT), clearance (Cl), volume of 291 292 distribution (V) and half-life of the terminal phase $(t_{1/2z})$. In addition, the relative oral 293 bioavailability (Fr) of docetaxel was calculated using the ratio of dose-normalized AUC values 294 following oral and i.v. administrations:

295

Fr (%)=AUC_{oral}/ AUC_{i.v} x 100 (Eq.5)

296 Where AUC_{oral} and AUC_{i.v.} correspond to the areas under the plasma curve for the oral and 297 intravenous (Taxotere[®]) administrations, respectively.

298 **2.6. Organ distribution of docetaxel**

299 To study the amount of anticancer drug in different organs after administration, animals received docetaxel loaded in the poly(anhydride) nanoparticles orally at a dose of 30 mg/kg. 300 301 Treatment groups were DTX-NP, DTX-NP2 and DTX-NP6. In addition, a group of mice was 302 treated intravenously with the commercial formulation, Taxotere®, at the same dose (30 303 mg/kg) as control. After administration, mice were sacrificed at different time points by cervical dislocation under isoflurane anesthesia (n=4 at each time point) and the following 304 305 organs were harvested: liver, spleen, kidneys, lung, heart, stomach and intestine. In the group receiving the commercial formulation, animals were sacrificed at 4, 12 and 24 hours 306 307 post-administration. The animals treated with the pegylated-poly(anhydride) nanoparticles 308 (DTX-NP2 and DTX-NP6) were sacrificed at 8, 24 and 72 hours post-administration. Finally, 309 for the DTX-NP group, the animals were killed at 8 h post-administration exclusively. Times 310 points were selected based on the plasmatic curves obtained for the different formulations 311 in mice.

Each tissue simple was kept on ice, accurately weighted in polystyrene tubes and homogenized in 1 ml of PBS pH 7.4 using a Mini-bead beater (BioSpect Products Inc, OK, USA). Later, the homogenized organs were centrifuged at 10,000xg for 10 minutes. The supernatants were then collected and stored at -80°C until further analysis by the HPLC assay.

The amount of docetaxel in each tissue was determined by liquid-liquid extraction method followed by reverse-phase HPLC analysis. The method for the extraction was adapted from Zhao et al. (2010). Standardized calibration curves were used for each organ. As internal standard, paclitaxel was used and the conversion of the DTX/PTX chromatographic areas to concentration was performed.

For extractions, aliquots (200 μ L) of the selected tissue samples were mixed with 25 μ L PTX solution (10 μ g/mL ethanol) for 1 min. Then, 3 ml t-buthylmethylether was added, and the resulting mixtures were vortex-mixing for 10 min. Next the mixture was centrifuged at 2,500xg for 10 min and the clear organic layer was transferred to a clean tube and evaporated until complete dryness. Finally, the residue was reconstituted with 125 μ L of acetonitrile-phosphate buffer (0.01 M; pH 2.1; 50:50 v/v) and quantified by HPLC-UV.

328 2.7. Statistical analysis

Data are expressed as the mean ± S.D of at least three experiments. The non-parametric Kruskal-Wallis followed by U Mann-Whitney test was used to investigate statistical differences. In all cases, p values less than 0.05 were considered to be statistically significant. All calculations were performed using GraphPad Prism 6.0 statistical software (GraphPad Software, CA, USA).

334

335 **3. Results**

336 **3.1.** Preparation and characterization of poly(anhydride) nanoparticles

Table 1 summarizes the main physico-chemical properties of the different poly(anhydride) 337 nanoparticles used in this work. Overall, pegylation of DTX-loaded nanoparticles slightly 338 decreased the mean size (220 nm for conventional and about 200 nm for pegylated 339 340 nanoparticles) and the negative zeta potential of the resulting nanoparticles (-43 mV vs. -35 341 mV). Besides, the polydispersity index (PDI) was lower than 0.2 and the yield of the process 342 was calculated to be between 60 and 65%. Empty nanoparticles displayed similar physicochemical characteristics than the DTX-loaded ones except for the yield of the process which 343 was slightly higher than in the presence of the anticancer drug (between 70 and 80%). 344 345 Similarly the mean size of empty nanoparticles was found to be slightly smaller than in the presence of docetaxel (see Table 1). 346

In addition, the amounts of PEG associated with the poly(anhydride) nanoparticles were 347 quantified by HPLC-ELSD. The analysis revealed that the amount of PEGs associated to 348 349 nanoparticles was significantly higher when nanoparticles were pegylated with PEG6000 350 (~55 μ g/mg) than with PEG2000 (~40 μ g/mg) (p<0.05). Based on these calculations, the estimated values of PEG densities on the surface of nanoparticles decreased with increasing 351 the length of the PEG chain. Thus, d_{PEG} was about 3-times higher for nanoparticles pegylated 352 with PEG2000 than when PEG6000 (0.46 vs. 0.15 nm⁻²). On the other hand, as for both types 353 of nanoparticles D was smaller than the Flory Radius (data not shown), the PEG chains 354 355 adopted a "brush" conformation on the surface of both pegylated nanocarriers.

Regarding the amount of docetaxel loaded in the nanoparticles, the addition of glycine to conventional nanoparticles enhanced dramatically the docetaxel loading, making it 20-times higher than when conventional nanoparticles were prepared in absence of this amino acid

(data not shown). For conventional nanoparticles, docetaxel content was estimated in 60 μg DTX/mg NP. However, for pegylated nanoparticles (DTX-NP2 and DTX-NP6), the docetaxel payload significantly increased. Thus, for nanoparticles pegylated with PEG6000 the DTX content was around 90 μg DTX/mg NP, whereas for DTX-NP2 the drug loading was almost 2times higher than for "nacked" nanoparticles (approx. 111 μg/mg NP). The encapsulation efficiency for DTX-NP2 and DTX-NP6 nanoparticles was 60 and 78%, respectively, whereas for DTX-NP it was about 42%.

366 Figure 1 shows the microphotographs obtained by field emission scanning and energyfiltered transmission electron microscopy of the nanoparticles. In all cases, the apparent 367 sizes of nanoparticles were similar to the values obtained by photon correlation 368 369 spectroscopy. All the nanoparticles formulations displayed spherical shapes. Moreover, conventional nanoparticles presented a smooth or plain surface (Figure 1A) whereas 370 pegylated ones appeared to show a spongy and diffuse surface (Figures 1B and 1C). In 371 addition, from EFTEM analysis (Figure 1D), pegylated nanoparticles appeared as spherical 372 373 structures surrounded by a long and diffuse dark area.

374 X-ray photoelectron spectroscopy (XPS) technique quantified the elemental and average 375 chemical composition by measuring the binding energy of electrons associated with atoms 376 around 5-10 nm depth inside the polymeric surface. Fittings of the C1s spectra (atomic 377 orbital 1s of carbon) of the surface of the poly(anhydride) nanoparticles and its components were examined (Table 2). Comparing the different control nanoparticles (NP, NP2 and NP6), 378 379 when PEG was incorporated to the formulation, the content of C-O bonds progressively 380 increased from NP (11%) to NP2 (19%) and NP6 (21%) while the proportion of C=O and C-381 C/C-H bonds decreased. For the docetaxel-loaded formulations (DTX-NP, DTX-NP2 and DTX-382 NP6), the addition of PEG induced a decrease of the signal related to the presence of C=O

bonds (15% for DTX-NP and 8% for DTX-NP6). In parallel, pegylation of nanoparticles
produced an important increase on the percentage of C-O bond values and a decrease of the
C-C/C-H intensity (Table 2).

Regarding the surface elemental composition (in atomic percentage values) of the samples, the carbon and oxygen content was very similar in all control formulations (NP, NP2 and NP6). However, the nitrogen signal is only detected in loaded-DTX nanoparticles (DTX-NP, DTX-NP2 and DTX-NP6). Thus, the nitrogen content progressively decreased when PEG was added to these loaded formulations while the oxygen content increased.

391 **3.2.** *In vitro* release study

Figure 2 depicts the release profiles of docetaxel from the different formulations expressed 392 as cumulative percentage of drug released as a function of time. In all cases, when 393 394 nanoparticles were incubated in SGF, no drug release was observed. In contrast, when nanoparticles were dispersed in the SIF, docetaxel was released. For DTX-NP2 the release 395 pattern in SIF was characterized by an important burst effect of about 75% of the loaded 396 397 drug in the first 30 min followed by a more sustained deliverance phase up to 10 hours. On 398 the other hand, for DTX-NP and DTX-NP6, the release curves of docetaxel in SIF exhibited a 399 slower discharge of docetaxel than DTX-NP2 followed by a more steady release up to the 400 end of the study in which almost all of their cargo was extracted. In any case, 1 h after the 401 incubation of nanoparticles in SIF, the amount of docetaxel released from DTX-NP6 was 402 about 65% of the loaded drug whereas for DTX-NP, only 55% of the drug was released.

The release profiles of DTX from nanoparticles were evaluated by fitting the *in vitro* data into various kinetic models (Table 3). For DTX-NP and DTX-NP2, the experimental data of the docetaxel release in SIF fitted well into the Korsmeyer-Peppas equation (Eq.2) with regression coefficients higher than 0.98. For both nanoparticle formulations, the release

407 exponent (n) was calculated to be lower than 0.5. For DTX-NP6, the data were adequately
408 adjusted to the three models. The obtained r² values for these models were around 0.8.
409 However, the calculated "n" value in the Korsmeyer-Peppas equation, was about 0.8 (Table
410 3).

411 **3.3.** Pharmacokinetic studies

412 The plasma concentration-time profile of docetaxel after iv administration of Taxotere® 413 (single dose of 30 mg/Kg) to female Balb/c mice is shown in Figure 3. The drug plasma 414 concentration rapidly decreased in a biphasic way with time and data were adjusted to a non-compartmental model. Levels of docetaxel in plasma were quantifiable until 12 hours 415 post-administration. The estimated AUC was 140 µg h/ml with a maximum concentration 416 417 (C_{max}) of 198 µg/mL. The mean residence time (MRT) and the half-life of the terminal phase $(t_{1/2z})$ were estimated to be 1.5 hours. The clearance (CI) of docetaxel was 0.2 L/h/kg and the 418 volume of distribution (V) of the drug was about 0.5 L/kg (Table 4). 419

Figure 4 shows the plasma concentration versus time profiles after oral administration of 420 421 docetaxel (single dose of 30 mg/kg) to Balb/c mice when administered as commercial 422 Taxotere[®] or encapsulated in the different poly(anhydride) nanoparticle formulations. When 423 Taxotere[®] was orally administered to mice, docetaxel plasma levels were found to be always 424 below the quantification limit of the chromatographic analytical technique. On the contrary, 425 when docetaxel was loaded in nanoparticles, these formulations displayed sustained plasma levels. In all cases, there was an initial rapid rise in the anticancer plasma levels for the first 2 426 hours, reaching the $C_{\mbox{\scriptsize max}}$ this was followed by a slow decline which was prolonged for at 427 428 least 8 hours for DTX-NP, and about 70 hours for the PEG containing formulations (DTX-NP2 429 and DTX-NP6). Comparing DTX-NP2 with DTX-NP6, DTX-NP2 provided slightly higher levels of 430 the anticancer drug than those determined for DTX-NP6. Another important fact to highlight

was that, for both nanoparticle formulations, the docetaxel plasma levels were within the
therapeutic window. For docetaxel, in rodents, this therapeutic window would be between
35 ng/mL (minimum effective dose) and 2700 ng/mL (maximum tolerated dose) [Mei et al.,
2013].

435 Table 4 summarizes the pharmacokinetic parameters calculated with a non-compartmental 436 analysis of the experimental data obtained after the administration of the different 437 docetaxel formulations to mice. For DTX-NP2 and DTX-NP6, AUC values were respectively 6.5 and 5-fold higher than the AUC obtained for non-pegylated nanoparticles (DTX-NP), 438 demonstrating a higher capability to promote the oral absorption of the taxane. In addition, 439 C_{max} values of docetaxel in the poly(anhydride) nanoparticles was between 1.3 and 2 μ g/ml. 440 The rank order of this parameter was DTX-NP6 > DTX-NP2 > DTX-NP. Moreover, the C_{max} was 441 442 reached at 0.08 h for DTX-NP,1.5-2 h for DTX-NP6 and DTX-NP2. Furthermore, the mean residence time (MRT) of the drug in plasma and the half-life of the terminal phase $(t_{1/2z})$ 443 were found to be similar for pegylated nanoparticles (both DTX-NP2 and DTX-NP6). 444 445 Interestingly, for all the formulations and routes of administration tested, the clearance of 446 docetaxel displayed a similar value (about 0.2 L/h/kg). On the contrary, the volumen of 447 distribution (V) of the anticancer drug was about 10 times higher when loaded in pegylated nanoparticles than for DTX-NP and Taxotere® intravenously administered. Finally, the 448 449 relative oral bioavailability of docetaxel delivered in pegylated nanoparticles was calculated 450 to be around 24% for DTX-NP6 and 32% DTX-NP2. For control nanoparticles, the oral 451 bioavailability was found to be of about 5%.

452 **3.4. Organ distribution of docetaxel**

453 Organ distribution of docetaxel was evaluated in Balb/c mice after the administration of a 454 single dose (30 mg/kg) either intravenously as Taxotere[®] or orally after encapsulation in

at different times after administration. For i.v. Taxotere[®], the highest concentration of docetaxel 4 h post-administration was found in the spleen (about 31 μ g DTX/g tissue) and the liver (about 24 μ g DTX/g tissue). Also, an important and similar amount of drug was quantified in the kidneys, lung and heart (about 16-18 μ g DTX/g tissue). These levels decreased rapidly with time and 24 h post-administration only significant amounts of docetaxel were quantified in spleen (about 10 μ g DTX/g tissue).

For DTX-NP2 and DTX-NP6 orally administered, the amount of the drug recovered in the different organs of animals was similar for both formulations. Thus, 24 hours after administration, docetaxel was mainly found in spleen and liver (~20 µg DTX/g tissue), followed by intestine (~18 µg DTX/g tissue), lung and kidneys (~13 µg DTX /g tissue). As time increased, the drug amounts in tissues decreased, even so, 72 hours post-administration significant amounts of docetaxel were still quantified in the spleen, lung and kidneys (about 5 µg DTX /g tissue).

Figure 6 represents the amount of docetaxel recovered in different organs of animals 8 h 469 470 after the administration of a single dose of the anticancer drug (30 mg/kg) formulated in nanoparticles or as Taxotere[®]. Overall, 8 h post-administration the amounts of anticancer 471 drug found in the liver, lungs and gut for pegylated nanoparticles (DTX-NP2 and DTX-NP6), 472 473 were higher than for Taxotere[®]. Thus, the liver of animals treated with docetaxel orally as 474 pegylated nanoparticles displayed 3-times more drug than when intravenously administered as Taxotere[®]. By contrast, 8 h post-administration, the levels of docetaxel when 475 administered in conventional nanoparticles (DTX-NP) were dramatically low, close to the 476 quantification limit of the HPLC technique (280 ng/mL). 477

478 Focusing on the differences observed amongst nanoparticles, there were not significant

479 differences between DTX-NP2 and DTX-NP6 for all the organs tested.

480

481 **4. Discussion**

The oral bioavailability of taxanes (e.g. docetaxel) is hampered by both their high lipophilic 482 character and low permeability related to their affinity to the P-glycoprotein and 483 484 cytochrome P450 enzymatic complex [Wu et al., 2011; Malingré et al., 2001]. In order to 485 solve these problems and thus enhance the oral absorption of these drugs, one possible 486 solution may be the encapsulation of these drugs into polymeric nanoparticles with both mucus-penetrating properties and inhibitory abilities of the efflux pump activity and 487 cythocrome P450 metabolism. The pegylation of nanoparticles from the copolymer of 488 methyl vinyl ether and maleic anhydride yields submicronic carriers with these capabilities 489 490 [Yoncheva et al., 2005; Inchaurraga et al., 2015]. In addition, acute and sub-acute toxicity studies in rats clearly demonstrated the absence of toxic or side effects when these 491 nanoparticles were orally administered [Ojer et al., 2012]. In the present work, our aim was 492 493 to gain more insight about the structure and composition of these pegylated nanoparticles as well as explore their potential as oral delivery systems for docetaxel. 494

Pegylation of poly(anhydride) nanoparticles slightly decreased the mean size and the negative zeta potential of "naked" nanoparticles (Table 1). Furthermore, the amount of PEG associated to the nanoparticles was significantly higher when nanoparticles were pegylated with PEG6000 than with PEG2000. This observation is in line with previous reported data [Zabaleta et al., 2012; Inchaurraga et al., 2015], in which it was described a higher degree of pegylation by increasing the MW of the PEG. All PEG-coated nanoparticles used have their PEG chains in a "brush" conformation, independent of the PEG chain molecular weight. 502 Regarding the encapsulation of docetaxel in nanoparticles, glycine and EDTA were employed 503 to increase its loading into the resulting nanoparticles. Thus, when the amino acid and the chelating agent was added to the medium in which the nanoparticles were obtained, the 504 drug loading was about 20-30 times higher than in the absence of both auxiliary excipients 505 506 (about 3 μ g/mg nanoparticles). The chelating agent would prevent the opening of the 507 anhydride groups by the presence of bivalent cations, whereas glycine would promote the 508 encapsulation of docetaxel in the resulting nanoparticles. In fact, the addition of glycine 509 would alter the solvent properties of the mixture in which the nanoparticles are formed, decreasing the solubility of the polymer in this medium and facilitating the interaction 510 between the polymer and docetaxel by hydrophobic bonds. A similar effect has been 511 512 observed by adding glycine to different kinds of micelles, generating important increases of 513 their capability to load hydrophobic compounds (i.e., quercetin) [Ruiz et al., 2008; Pillai et 514 al., 2016].

On the other hand, the docetaxel loading was also found to be dependent on both the 515 516 presence and MW of PEG employed for pegylation. In this way, the use of PEG2000 allowed us to increase almost 2-times the docetaxel payload compared to "naked" nanoparticles. 517 518 These results agree well with previous studies with PLGA/PLA particles [Enolw et al., 2011], 519 which reported a significant increase of docetaxel loading in pegylated PLGA/PLA delivery 520 systems, in comparison with the conventional ones, due to the solubilising properties of 521 PEG. In addition, PEG2000 appeared to be slightly superior for increasing the docetaxel 522 entrapment in poly(anhydride) nanoparticles.

523 From the observations by electronic microscopy techniques (Figure 1), these pegylated 524 nanocarriers would adopt a structure based on a solid core surrounded by a PEG corona. In 525 order to study this structure, the surface of nanoparticles was examinated by XPS analysis

526 (Table 2). Comparing "naked" nanoparticles (NP) with pegylated ones (NP2 and NP6), the percentage of C-O bonds, which are typical in the poly(ethylene glycol) structure [Baer and 527 Engelhard, 2010], increased after nanoparticle pegylation. In addition, NP6 produced a 528 slightly more intense signal of C-C/C-H bonds than NP2. This observation would be related to 529 a longer C-C/C-H chain for PEG6000 than for PEG2000. When docetaxel was loaded into 530 531 "naked" nanoparticles (DTX-NP), an increase in the XPS signals related with the presence of 532 C-N bonds was found. This fact would be due to the presence of both the anticancer drug 533 and glycine. Additionally, the presence of docetaxel and glycine also induces a reduction in the percentages of C-C/C-H and C=O bonds, as compared with NP. For pegylated 534 nanoparticles, the presence of PEG at the surface of nanoparticles would hinder the access 535 536 and, therefore, the binding of glycine to the surface of nanoparticles. In the case of DTX-NP2, this finding would be supported by a decrease of the nitrogen content for these 537 nanoparticles (as compared with DTX-NP) as well as by the decrease in the percentage of C-538 N/C-O bonds that can be attributed to the substitution of glycine by PEG. Finally, for DTX-539 540 NP6, elemental analysis displayed a very low amount of nitrogen associated with a high 541 content of oxygen. In addition, these nanoparticles showed a low percentage of C=O and C-542 C/C-H bonds and a quite high content of C-N/C-O bonds. These last observations would be 543 related to the presence of the PEG chains at the surface of nanoparticles. To sum up, the 544 reduction of the nitrogen content would be associated to the presence of PEG in the 545 samples. In addition, the presence of longer PEG chains would be reflected by an increase in 546 the percentage of C-N/C-O bonds. Moreover, the decrease in the percentage of C=O bonds 547 (typical for anhydride residues) observed for pegylated nanoparticles (mainly for those 548 pegylated with PEG 6000) would be directly related to the particular characteristics of the 549 XPS technique, which is adapted to the investigation of the surface properties of a given 550 material [Baer and Engelhard, 2010]. All together would probe that pegylation of these 551 poly(anhydride) nanoparticles yields a PEG coating.

552 Docetaxel release profiles from nanoparticle formulations were evaluated in simulated gastric and intestinal fluids, both containing Tween 80 as solubilising agent. In all cases, no 553 554 drug release was observed when nanoparticles were incubated in acid conditions. However, 555 under simulated intestinal pH conditions, docetaxel was rapidly released with small 556 differences between "naked" and pegylated nanoparticles. Thus, pegylated nanoparticles 557 displayed profiles characterized by an initial release pulse of 65-75% of the loaded drug followed by a slow deliverance phase of the remaining drug. For DTX-NP, the curve was 558 characterized by an initial burst effect of about 40% followed by a sustained and continuous 559 560 release step. Interestingly, the release pulse was almost immediate for DTX-NP2 formulation 561 whereas, for nanoparticles pegylated with PEG6000 the burst effect only appeared after 1 h of incubation in SIF. Analysis of the release data also highlighted a different behaviour 562 between nanoparticle formulations. The release of docetaxel from DTX-NP and DTX-NP2, 563 characterised by a Korsmeyer-Peppas exponent coefficient lower than 0.5, would be 564 explained by a quasi-Fickian Higuchi diffusion mechanism, typical of matrix-type devices. On 565 566 the contrary, the mechanism involved in the release of docetaxel from DTX-NP6 (with a Korsmeyer-Peppas coefficient of 0.8) would be a combination between diffusion and 567 568 erosion. In this case, the presence of long chains of poly(ethylene glycol) at the surface of 569 the nanoparticles would hamper the diffusion of the loaded drug. So the release of the 570 loaded drug will be delayed until the nanoparticle matrix will start to be eroded/dissolved.

571 For the pharmacokinetic study in mice, a single dose of 30 mg docetaxel per kg bw was 572 selected. Taxotere[®], intravenously administered, presented a characteristic nonlinear profile 573 (Figure 3) that has been previously reported by other authors [Nieuweboer et al., 2015; Van

574 Tellingen et al., 1999] and associated with the effect of micellar entrapment on DTX in presence of Tween[®] 80 in the formulation, which could affect the distribution of unbound 575 drug [Nassar et al., 2011; Desai et al., 2008]. At the administered dose, the plasmatic levels 576 of docetaxel diminished rapidly, and 12 hours post-administration, no levels of the drug 577 578 were quantified. The non-linearity was caused mainly during the first hours after drug 579 administration when the concentrations were relatively high. From this curve, the mean AUC 580 and the half-life of the terminal phase $(t_{1/2z})$ for docetaxel were estimated to be about 140 581 μ g h/ mL and 1.5 hours, respectively. The volume of distribution (V) was 0.5 L/h and clearance (CI) was 0.2 L/h/kg. These results are consistent with data previously published by 582 Van Tellingen et al. (1999), who administered Taxotere® at similar dose level (33 mg 583 docetaxel per kg bw) in female FVB mice. In contrast, when commercial Taxotere® was 584 585 administered orally, the drug plasma levels were below the quantification limit of our technique. In any case, the oral bioavailability of docetaxel in mice has been previously 586 reported to be around 3.6% [Bardelmeijer et al., 2002]. 587

When docetaxel was orally administered after encapsulation in pegylated nanoparticles, the 588 589 plasma levels of the anticancer drug were high and sustained in time till 3 days. For "naked" 590 nanoparticles, the docetaxel plasma concentration was initially high but decreased rapidly and no quantifiable levels were found 12 h after administration. More importantly, the 591 592 docetaxel plasma levels provided by pegylated nanoparticles were found to be within the 593 therapeutic window [Saremi et al., 2011; Mei et al., 2013]. This observation is particularly 594 interesting for an oral docetaxel treatment that would permit to achieve long-term drug 595 exposure and predicted responses [Bruno et al., 1998]. Moreover, the half-life of the drug 596 was greatly extended from 1.5 h for intravenous administration to 35 h for oral 597 administration of pegylated nanoparticles (Table 4). This may be due to the capability of

598 pegylated nanoparticles to reach the surface of the enterocyte, therefore prolonging their residence at the site of absorption. Another important fact was that the metabolism of 599 docetaxel appeared to be not affected when it was carried by the nanoparticles (p<0.01). In 600 fact, the clearance of docetaxel from DTX-NP and pegylated nanoparticles was similar to the 601 value calculated from the i.v. administration of Taxotere®. Compared to DTX-NP, pegylated 602 603 nanoparticles increased the drug elimination half-life, mean residence time (MRT) and 604 volume of distribution (V) (Table 4). These results would corroborate that when docetaxel is 605 loaded into pegylated nanoparticles, the drug has sustained release, prolonged half-life and increased tissue appetency. As a consequence, the relative oral bioavailability obtained for 606 the different pegylated nanoparticles were high, varying from 24 to 33% for DTX-NP6 and 607 608 DTX-NP2 respectively. These bioavailability results are slightly higher than others reported 609 previously using solid lipid nanoparticles [Cho et al., 2014] or self-nano-emulsifying drug delivery systems [Seo et al., 2013]. Nevertheless, the bioavailability of docetaxel in pegylated 610 nanoparticles was lower than the value reported by Feng et al. (2009) with poly(lactide)-611 612 vitamin E TPGS/montmorillonite nanoparticles on SD rats (about 90%).

The distribution of the orally administered docetaxel, when loaded into pegylated nanoparticles, appeared to be quite similar to that elicited by Taxotere[®] (Figures 5 and 6). The comparative evaluation of the drug levels in different organs was quite similar for both intravenous Taxotere[®] and pegylated nanoparticles; although this similar trend was delayed in time for the oral treatments. In both cases, docetaxel accumulates in the liver, spleen, lungs, intestine and kidneys. The main difference, if any, is the decreased levels of docetaxel observed in the hearts of animals treated orally with pegylated nanoparticles (Figure 6).

All together these results suggest that pegylated nanoparticles, after reaching the surface of
 the enterocytes, would release the loaded docetaxel and, in parallel, disturb the effect of P-

622 gp and cytochrome P450. Obviously, the possibility that these pegylated nanoparticles penetrate the enterocytes cannot be discarded; although their absorption through the blood 623 and/or lymphatic routes would be unlikely. This idea would be supported by the similar 624 elimination (clearance) and distribution of docetaxel in vivo from pegylated nanoparticles 625 and intravenous Taxotere[®]. Another factor supporting this explanation would be that these 626 627 pegylated nanoparticles when incubated with Caco-2 cells were not capable to be 628 internalized [Ojer et al., 2013]. In line with this, biodistribution studies of these pegylated 629 nanoparticles (radiolabelled with technetium-99m) demonstrated that the localization of these carriers after oral administration was restricted to the gut [Ojer et al., 2012]. It is also 630 important to take into account that the drug plasma levels are in line with the intestinal cell 631 632 renewal cycle, which takes 3-5 days [Barker, 2014]. Furthermore, in an aqueous medium at 633 neutral/basic pH, the anhydride residues of the polymer used to prepare our nanoparticles (Gantrez® AN) suffer from hydrolysis yielding carboxylic groups. Under these conditions, the 634 ionization of these -COOH groups would induce a swelling of the nanoparticle shell 635 636 facilitating the drug release and hampering its entry into the cells. In any case, the behaviour 637 of pegylated nanoparticles would be different to that proposed for PLGA nanocapsules 638 [Attili-Qadri et al., 2013] or solid lipid nanoparticles [Cho et al., 2014]. In these cases, these nanodevices would penetrate into the enterocytes and move into the circulation via the 639 640 lymphatic system [Attili-Qadri et al., 2013]. Probably, the lipid character of the oily core of 641 these nanoparticles would favour this particular behaviour.

In summary, pegylated nanoparticles provide an adequate device for the oral delivery of docetaxel. When orally administered, these nanoparticles offered prolonged and sustained plasma levels of the anticancer drug for 3 days. In addition, the relative oral bioavailability was calculated to be up to 32% and between 5 and 6-times higher than for "naked"

646 nanoparticles. Interestingly, the elimination and distribution of docetaxel in vivo from 647 pegylated nanoparticles and intravenous Taxotere[®] was found to be similar, suggesting that 648 these nanoparticles would remain within the gut after reaching the surface of the 649 enterocytes and would not enter into the circulation.

657 Disclosures section

Portions of this manuscript were presented and published in thesis form (Pegylated nanoparticles to falicitate the intravenous-to-oral switch in docetaxel cancer chemotherapy) in fulfillment of the requirements for the PhD for Student Miss Luisa Ruiz-Gatón from University of Navarra.

662 The authors declare no conflict of interest.

803 Figure Legends

Figure 1. Field emission scanning electron microscopy (FESEM) and energy-filtered transmision electron microscopy (EFTEM) images of the different poly(anhydride) nanoparticles loaded with docetaxel. FESEM image of DTX-NP (A), DTX-NP6 (B) and DTX-NP2 (C). EFTEM image of DTX-NP2 (D).

Figure 2. Docetaxel release profiles from the poly(anhydride) nanoparticles formulations
after incubation in simulated gastric fluid (SGF) and simulated intestinal fluid (SIF) at 37°C.
Data represented as mean ± S.D. (n=4).

Figure 3. Docetaxel plasma concentration-time profile after a single intravenous dose in Balb/c mice (30 mg/kg) dose of the commercially available formulation Taxotere[®]. Data are expressed as mean ± S.D., n=4 per time point.

Figure 4. Docetaxel plasma levels as a function of time after the oral administration of nanoparticle formulations as a single dose of 30 mg/kg bw in Balb/c mice. Data are expressed as mean \pm S.D., n=4 per time point.

Figure 5. Organ distribution time profiles of docetaxel in Balb/c mice after i.v. administration of Taxotere[®] (A) or oral administration of docetaxel loaded in pegylated nanoparticles with either PEG2000 (B) or PEG6000 (C). All mice received a single dose of 30 mg/kg. Data are expressed as mean ± S.D. (n=4).

Figure 6. Comparative organ distribution of docetaxel following the oral administration of the different poly(anhydride) nanoparticles loaded with docetaxel and the intravenous administration of Taxotere[®] at 8 hours after administration in Balb/c mice. All mice received a single dose of 30 mg/kg. Data are expressed as mean ± S.D. (n=4). *p<0.05 Taxotere[®] vs. nanoparticle formulations: DTX-NP, DTX-NP2 and DTX-NP6.
