Highly volatile and valuable reagents, perfluoroiodides were shown to complex with ionic liquids with aid of a halogen-bond between a diverse set of anions and electrophilic iodine atom in perfluorinated iodides. The affinity of anions in various ionic liquids towards perfluoroiodides was examined by ¹⁹F NMR. Making use of the non-volatility of ionic liquids, we demonstrate here, perfluoroiodides can be stored and released controllably, on demand, from an ionic liquid matrix.

The capture and controlled release of substances play a vital part in the day to day life. Fluorinated organic molecules are increasingly useful in medicinal chemistry, agro chemistry, and materials science.¹ Many recent advances in fluoroorganic chemistry² are due to emerging reagents that are safer, less toxic with improved selectivity. The vast majority of perfluoroalkylating reagents reported in the literature are mainly trifluoromethylating reagents. They are structurally diverse in nature, including silicon containing agents, metallo-agents and completely organoreagents.^{3–8} Perfluoroalkyl iodides, in particular, CF₃I and CF₃CF₂I,⁹ are useful but gaseous sources of perfluoroalkyl fragments. Consequently, handling gaseous or volatile compounds like CF₃I, C₂F₅I, C₃F₇I and C₄F₉I is cumbersome. Stock solutions of CF₃I in conventional organic solvents cannot be stored without the quick decline of perfluoroiodides over a period of time. The inherent volatility of common organic solvents and the lack of any form of ‘conventional bonding’ between the substrate and the solvent add further difficulties in working with these materials. Very recently, super basic amines such as teramethylguanidines have been shown to complex perfluoroiodides efficiently *via* halogen-bonding,¹⁰ though long-term storage of such iodides in strongly basic materials may lead to undesirable side-reactions. Furthermore, these amines also possess some volatility. Increasingly, halogen bonding¹¹ has been shown to facilitate the assembly of diverse hosts and guests,

leading to some applications. In a recent publication, it was shown that quaternary ammonium iodides were able to resolve mixtures of perfluorodiiiodides and mediated by halogen-bonding.¹²

In this respect, appropriately designed ionic liquids have been given scant attention in their utilisation in capturing and delivering materials such as perfumes¹³ and expensive fluorinating agents. There is an example in the literature describing the capture of trifluoromethane mediated by ionic liquids.¹⁴ The forces of attraction of such compounds towards ionic liquids are, however, likely to be weak and elusory in nature. Chloride containing ionic liquids were shown, recently, to capture Cl₂ gas forming Cl₃ anion via covalent bonding.¹⁵ In this respect, it would be desirable to have appropriately designed ionic liquids targeting specific bonding to parts of a compound, without affecting their integrity to store and deliver volatile perfluoro compounds on demand. Such a concept is illustrated in Figure 1.

Figure 1: An illustration to show a possible binding mode involving a halogen bond for an ‘iodide’ ionic liquid interacting with a perfluoro iodide.

In this communication, we describe a set of carefully chosen ionic liquids (see Scheme 1) bearing a set of diverse anions, in particular, iodide anions where the cations are chosen in order to

minimise cation-halide interactions yet maintaining maximum fluidity. Some of these ionic liquids are low melting solids (melting points < 70 °C). Syntheses of all the ionic liquids, given in scheme 1, were fairly straightforward and they were characterised by standard analytical techniques. (**1**) is a room temperature ionic liquid ($T_g = -62.3$ °C), except [bmim] chloride, bromide and iodide all others were liquids at room temperature.

All ionic liquids described in Scheme 1 were allowed to interact with, initially, C_4F_9I in the neat state (mole ratio; IL: $C_4F_9I = 1.2:1$) and then analysed by ^{19}F NMR spectroscopy. Two such examples of ^{19}F NMR spectra of (**1**) and [bmim]I with C_4F_9I are given in Figure 2. The interaction of electrophilic iodine atom in C_4F_9I with the anions of two ionic liquids can be seen by the large shift of ^{19}F signal corresponds to $-CF_2I$; with (**1**) $\Delta\delta$ of 13.1 and with [bmim]I $\Delta\delta$ of 10.4 was observed.

Figure 2: Partial ^{19}F nmr spectra of **Top:** a mixture of C_4F_9I and [bmim]I; **bottom:** a mixture of C_4F_9I and ionic liquid, **1**.

These chemical shift changes are significantly high indicating the strong halogen bonding interactions between iodide anion in both ionic liquids and the perfluoroiodide. Higher polarisability of the iodide,¹⁶ hence, its ability to donate electrons easily towards more electrophilic centres is well documented and probably, accounts for its ability to form stronger halogen bonds. Armed with these initial findings, we carried out a comprehensive ^{19}F nmr study with a broad range of ionic liquids carrying a diverse collection of anions. The results are given in figure 3. The vast majority of the cations

were 1-butyl-3-methylimidazolium (bmim) except for cations present in ionic liquid **11** and **14** (these numbers refer to Fig. 3); viz methyl-tris[2-(2-methoxyethoxy)ethyl]ammonium].

Figure 3: Partial ^{19}F NMR spectra of mixtures of C_4F_9I and ionic liquids $[C]^+[X]^-$ where C = 1-butyl-3-methylimidazolium (bmim) for **2-10,12,13**; C = methyltris[2-(2-methoxyethoxy)ethyl]ammonium for **11, 14**; The anion $[X]^-$ in **2**, $CF_3SO_3^-$; **3**, $MeOSO_3^-$; **4**, $N(CN)_2^-$; **5**, $CF_3CO_2^-$; **6**, SCN^- ; **7**, $(MeO)_2PO_2^-$; **8**, I^- ; **9**, Br^- ; **10**, Cl^- ; **1**, neat C_4F_9I . In all cases, ^{19}F NMR spectra were run with a $dmso-d_6$ external lock.

All the nmr spectra shown in figure 3 were recorded on mixtures of neat ionic liquids and neat C_4F_9I with a sealed capillary filled with $dmso-d_6$ as an external lock. As expected, anions such as $CF_3SO_3^-$ and $CH_3SO_3^-$ formed weaker interaction with C_4F_9I due to their charge distribution leading to low charge densities on oxygens. Unsurprisingly, halide anions and acetate anion showed a higher affinity towards halogen bonding to perfluoroiodide. This may be due to better orbital energy matching and overlap with such anions. It is noteworthy that the H-bonding affinity with some of these anions are strongly related, albeit indirectly, to the ability to dissolve cellulose.¹⁷

$\Delta\delta$ shifts of $-CF_2I$ in C_4F_9I [bmim][X]

Figure 4: A histogram of ^{19}F NMR chemical shift changes, $\Delta\delta$, of the $-CF_2I$ group in C_4F_9I in [bmim][X] where X = $MeOSO_3^-$; $N(CN)_2^-$; $CF_3CO_2^-$; SCN^- ; I^- ; Br^- ; Cl^- ; $CH_3CO_2^-$. N.B. [bmim][NTf₂] was eliminated from the study due to its phase separation with C_4F_9I

The histogram shown in figure 4 gives an indicative synopsis of the $\Delta\delta$ values for different anions interacting with C_4F_9I . All cations associated with these anions were kept constant which is $[bmim]^+$. Acetate appears to lend the largest $\Delta\delta$ while all halide anions impart similarly large $\Delta\delta$ changes. As the negative charge on acetate is equally shared between two oxygen atoms, it provides the opportunity to form bifurcated halogen bonds¹⁸ with electrophilic iodine atom. This may account for acetate displaying a stronger interaction. Furthermore, the presence of trace amounts of water in $[bmim][OAc]$ does not appear to have a significant effect on the $\Delta\delta$, as can be evidenced from the last two columns on the right, in figure 4. Moreover, halogen bonding originating from halide to halogen is relatively common whereas halogen bonding to other negatively charged or electron rich atoms is less common.¹⁹ According to the findings summarised in figure 4, the weakest interactions were found with methylsulfate and dicyanamide anions. This could be attributed to negative charge distribution in such anions among many atoms.

Next, we focussed our attention to the controlled release of C_4F_9I from ionic liquid matrixes under thermal conditions. An initial experiment was performed, with an IL/ C_4F_9I mixture having a molar ratio of (1): C_4F_9I = 1.2:1, within a Thermogravimetric Analysis (TGA) instrument. Static conditions at 25 °C with a nitrogen flow of 1 ml m⁻¹ was maintained throughout the experiment. A blank experiment was also performed just with C_4F_9I without the ionic liquid under identical conditions. The results are given in figure 5 showing the swift disappearance (< 4 m; red line) of the perfluoroiodide in the absence of the ionic liquid whereas the (1) is able to retain C_4F_9I for 150 m (navy blue line).

Consequently, a series of experiments were performed, in an apparatus shown in ESI-figure S2, with ten ionic liquids where C_4F_9I was dissolved maintaining the same molar ratio as before. All experiments were performed at 40 °C and the

Figure 5: A plot of normalised weight loss against time for C_4F_9I (a), Red in the absence of any ionic liquid, (b) Navy blue, in the presence of ionic liquid (5). The molar ratio of IL: C_4F_9I = 1.2:1 and the plots were obtained using static thermogravimetric analysis (TGA) in a TGA instrument at 25 °C, with a nitrogen flow of 1 ml m⁻¹.

release of C_4F_9I were monitored with time, gravimetrically, without N_2 flowing over the sample. The kinetic profiles of the release of C_4F_9I for all experiments are given in figure 6. There is a cluster of six lines congregating at the top which are all halide containing ionic liquids, except $[bmim][CH_3CO_2]$, binding tightly to the perfluoroiodide with stronger halogen bonding. $[Bmim][CF_3CO_2]$ and $[bmim][CF_3SO_3]$ appears to have the weakest hold on the perfluoroiodide. The weaker donor ability

Figure 6: Release profiles of perfluoroiodobutane from a set of ionic liquids with diverse anions, performed at 40 °C in an apparatus shown in figure S2 in ESI. In all cases the molar ratio of ionic liquid: C_4F_9I = 1.2:1.0. The weight loss (as a percentage) was measured gravimetrically using a four-figure balance.

COMMUNICATION

of fluorinated anions is well known which could account for this observation. The viscosity of ionic liquids, however, may also play a role in affecting the mass transport of such volatile materials embedded in their domain. Therefore, apart from halogen bonding interactions, the contribution emanating from the viscosity of the matrix cannot be discounted in the delivery process.

In conclusion, we have described here the versatility of some ionic liquids to be utilised as storage media or 'surrogates' for volatile, expensive and commonly used perfluoroiodides without affecting the integrity of these reagents. We have used ^{19}F NMR effectively to investigate the degree of interaction between perfluoro-reagents and ionic liquids. It is also demonstrated how these materials could be released in a controllable manner, on demand, by virtue of gentle heat. These reagents can be stored, at room temperature, in suitable ionic liquids for months without any significant material loss.

The authors wish to thank Richard Murphy for assistance with NMR spectra, Angela Brownlee for TGA and DSC and George Burton for designing and constructing the glass apparatus that was used for experiments involving releasing perfluoroiodide. HQNG acknowledges the constant support and encouragement given to him by the late co-author, Prof. Kenneth R. Seddon.
