ABSTRACT

Background

A variety of minimally invasive surgical approaches are available as an alternative to transurethral resection of prostate (TURP) for the management of lower urinary tract symptoms (LUTS) in men with benign prostatic hyperplasia (BPH). A recent addition to these is prostatic urethral lift (PUL).

Objectives

To assess the effects of PUL for the treatment of LUTS in men with BPH.

Search methods

We performed a comprehensive search of multiple databases (the Cochrane Library, MEDLINE, Embase, LILACS, Scopus, Web of Science, and Google Scholar), trials registries, other sources of grey literature, and conference proceedings with no restrictions on the language of publication or publication status up until 31 January 2019.

Selection criteria

We included parallel group randomized controlled trials (RCTs). While we planned to include non-RCTs if RCTs had provided low-certainty evidence for a given outcome and comparison, we could not find any non-RCTs.

Data collection and analysis

Two review authors independently screened the literature, extracted data, and assessed risk of bias. We performed statistical analyses using a random-effects model and interpreted them according to the Cochrane Handbook for Systematic Reviews of Interventions. We planned subgroup analyses by age, prostate volume, and severity of baseline symptoms. We used the GRADE approach to rate the certainty of the evidence.
Main results

We included two RCTs with 297 participants comparing PUL to sham surgery or TURP. The mean age was 65.6 years and mean International Prostate Symptom Score was 22.7. Mean prostate volume was 42.2 mL. We considered review outcomes measured up to and including 12 months after randomization as short-term and later than 12 months as long-term. For patient-reported outcomes, lower scores indicate more urological symptom improvement and higher quality of life. In contrast, higher scores refer to better erectile and ejaculatory function.

**PUL versus sham:** based on one study of 206 randomized participants with short follow-up (up to three months), PUL may lead to a clinically important improvement in urological symptom scores (mean difference (MD) -5.20, 95% confidence interval (CI) -7.44 to -2.96; low-certainty evidence) and likely improves quality of life (MD -1.20, 95% CI -1.67 to -0.73; moderate-certainty evidence). We are uncertain whether PUL increases major adverse events (very low-certainty evidence). There were no retreatments reported in either study group by three months. PUL likely results in little to no difference in erectile function (MD -1.40, 95% CI -3.24 to 0.44; moderate-certainty evidence) and ejaculatory function (MD 0.50, 95% CI -0.38 to 1.38; moderate-certainty evidence).

**PUL versus TURP:** based on one study of 91 randomized participants with a short follow-up (up to 12 months), PUL may result in a substantially lesser improvement in urological symptom scores than TURP (MD 4.50, 95% CI 1.10 to 7.90; low-certainty evidence). PUL may result in a slightly reduced or similar quality of life (MD 0.30, 95% CI -0.49 to 1.09; low-certainty evidence). We are very uncertain whether PUL may cause fewer major adverse events but increased retreatments (both very low-certainty evidence). PUL probably results in little to no difference in erectile function (MD 0.80, 95% CI -1.50 to 3.10; moderate-certainty evidence), but probably results in substantially better ejaculatory function (MD 5.00, 95% CI 3.08 to 6.92; moderate-certainty evidence). With regards to longer term follow-up (up to 24 months) based on one study of 91 randomized participants, PUL may result in a substantially lesser improvement in urological symptom score (MD 6.10, 95% CI 2.16 to 10.04; low-certainty evidence) and result in little worse to no difference in quality of life (MD 0.80, 95% CI 0.00 to 1.60; low-certainty evidence). The study did not report on major adverse events. We are very uncertain whether PUL increases retreatment (very low-certainty evidence). PUL likely results in little to no difference in erectile function (MD 1.60, 95% CI -0.80 to 4.00; moderate-certainty evidence), but may result in substantially better ejaculatory function (MD 4.30, 95% CI 2.17 to 6.43; low-certainty evidence).

We were unable to perform any of the predefined secondary analyses for either comparison.

We found no evidence for other comparisons such as PUL versus laser ablation or enucleation.

Authors’ conclusions

PUL appears less effective than TURP in improving urological symptoms both short-term and long term, while quality of life outcomes may be similar. The effect on erectile function appears similar but ejaculatory function may be better. We are uncertain about major adverse events short-term and found no long-term information. We are very uncertain about retreatment rates both short-term and long-term. We were unable to assess the effects of PUL in subgroups based on age, prostate size, or symptom severity and also could not assess how PUL compared to other surgical management approaches. Given the large numbers of alternative treatment modalities to treat men with LUTS secondary to BPH, this represents important information that should be shared with men considering surgical treatment.

**Plain Language Summary**

Prostatic urethral lift for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia

**Review question**

Does prostatic urethral lift (PUL) improve bothersome urinary symptoms without unwanted side effects in men with an enlarged prostate?

**Background**

Prostate enlargement is common in men as they get older and may cause difficulty with urination. PUL is a new procedure to relieve urinary symptoms such as having to urinate often, having to strain or not being able to empty the bladder completely. Unwanted side effects of treatment may be problems with erections, ejaculation or needing to be treated again. PUL works by placing little hooks that...
compress the tissue of the prostate to open up the urinary stream without the need to cut or remove any tissue. We did this review to compare PUL to other surgical treatments in men with an enlarged prostate and bothersome urinary symptoms.

**Study characteristics**

We included two randomized controlled studies (clinical trials where people are randomly put into one of two or more treatment groups) with 297 men comparing PUL to sham surgery (participants are made to believe they received treatment, while in reality they did not) or transurethral resection of prostate (TURP: removing the excess prostate growth using a camera and an electrically activated resecting loop inserted via the penis). The average age of the participants was 65.6 years.

**Key results**

Compared to sham surgery up to three months, PUL may improve urinary symptoms and likely improves quality of life without additional unwanted side effects after surgery. In the short term, there were no additional surgeries because PUL did not work. PUL likely does not make erections or ejaculation worse.

Compared to TURP up to 24 months, PUL may be less effective in relieving urinary symptoms, but result in similar quality of life. PUL may preserve ejaculation, but may have less unwanted effects on erections than TURP. However, we are either very uncertain or have no evidence about serious unwanted side effects or the need for additional treatment after surgery.

Findings of this review are up-to-date until 31 January, 2019.

**Certainty of the evidence**

The certainty of evidence for most outcomes was low. This means that the true effect may be substantially different from what this review shows.
SUMMARY OF FINDINGS FOR THE MAIN COMPARISON

PUL compared to TURP for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia (short term)

*The risk in the intervention group (and its 95% confidence interval) is based on the assumed risk in the comparison group and the relative effect of the intervention (and its 95% CI).

BPH: benign prostatic hyperplasia; CI: confidence interval; MD: mean difference; PUL: prostatic urethral lift; RCT: randomized controlled trial; RR: risk ratio; TURP: transurethral resection of prostate.

**GRADE Working Group grades of evidence**

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

---

*a Downgraded one level for study limitations: high risk of performance or detection bias, or both; high or unclear risk of attrition bias.

*b Downgraded one level for imprecision: confidence interval crossed assumed threshold of clinically important difference.

*c Downgraded one level for study limitations: high risk of performance bias.
*Downgraded two levels for imprecision: wide confidence interval crossed assumed threshold of clinically important difference.
Minimal clinically important difference: 25% improvement (greater than 2.5 points) from the baseline (PUL: 11; TURP: 9).
Background

Description of the condition

The prostate gland is an organ approximately the size of a walnut that is located below the urinary bladder encircling the urethra (Leissner 1979). Benign prostatic hyperplasia (BPH) is a histological diagnosis defined as an increased number of epithelial and stromal cells in the prostate; this may cause prostatic enlargement and subsequently compression of the urethra and obstruction (Roehrborn 2008a). Therefore, BPH may develop with or without lower urinary tract symptoms (LUTS) in men over the age of 40 years (Dunphy 2015). BPH receives clinical significance when associated with bothersome LUTS (Roehrborn 2008a). Symptom bother typically correlates with the increased number and severity of symptoms, which relates to both quality of life impairment and treatment seeking (Agarwal 2014). Self-administered questionnaires, namely International Prostate Symptom Score (IPSS), include the quality of life domain to evaluate the relative degree of bother across all LUTS (Barry 1995). Chapple 2017 reported that increasing LUTS severity was associated with worsening men’s overall distress using patient perception of bladder condition which is a single-item global question (ranging from 1 (causes no problems at all) to 6 (causes severe problems)). In this Cochrane Review, we considered the term BPH as prostatic enlargement with LUTS through which to define the disease condition and potential need for intervention.

BPH can progress and cause serious consequences such as acute urinary retention, urinary tract infection, and upper urinary tract deterioration. BPH also results in a negative impact on public health and a reduction in a person’s quality of life (Kozminski 2015; Martin 2014). In Europe, 30% of men over 50 years of age, equivalent to 26 million men, are affected by bothersome LUTS, including storage symptoms (such as urinary frequency, urgency, and nocturia) or voiding symptoms (such as urinary hesitancy, weak urinary stream, straining to void, and prolonged voiding), or both. The yearly reported associated number of medical prescriptions is estimated to be around 11.6 million for 74 million people at risk from 2004 to 2008 (Cornu 2010). The prevalence of LUTS, according to an international study involving 7588 men was 18% in the ages of 40s, 29% in the 50s, 40% in the 60s, and 56% in the 70s (Homma 1997). In the USA, an estimated eight million men older than 50 years of age have BPH (Roehrborn 2008b). More recent data showed that the lifetime prevalence of BPH was 26.2% (95% CI: 22.8-29.6%) (Lee 2017).

Diagnosis

Initial evaluation of LUTS suggestive of BPH includes patient history, physical examination including a digital rectal examination, urinalysis, prostate-specific antigen (PSA) blood test, voiding diary, and IPSS (EAU 2017; McVary 2011). A digital rectal examination is performed to assess the prostate for size, and for any lesions suspicious for cancer. The PSA is secreted by the prostate gland and is found to be abnormally elevated in conditions such as prostate cancer, BPH, infection, or inflammation of the prostate (EAU 2017; McVary 2011). The IPSS is used to assess urinary symptom severity and quality of life. It is also used to document subjective responses to treatment (Barry 1992; EAU 2017; McVary 2011). Measurement of maximum flow rate ($Q_{\text{max}}$) and postvoid residual (PVR) are also often used in diagnosis and treatment decisions (EAU 2017; McVary 2011). A low $Q_{\text{max}}$ and a large PVR predict an increased risk of symptom progression (Crawford 2006). Other tests include radiological imaging, urodynamic evaluation, and cystoscopy to further determine appropriate treatment and predict treatment response (Egan 2016; McVary 2011).

Treatment

Treatment decisions are based on symptoms and the degree of bother noted by the patient. Initial treatment options for BPH include conservative management (watchful waiting and lifestyle modification) and medication (alpha blockers and 5-alpha reductase inhibitors) (EAU 2017; McVary 2011). If patients have been refractory to conservative and medical treatment, or BPH causes subsequent complications, such as acute urinary retention, recurrent urinary tract infection, bladder stones or diverticula, haematuria, or renal insufficiency, surgical options are considered (EAU 2017; McVary 2011). Until the 1970s, the only option available to treat this condition and relieve LUTS was an open or endoscopic surgery with the aim of removing or resecting prostatic tissue to open up the blocked urethra (Pariser 2015). Clinical guidelines recommend monopolar or bipolar transurethral resection of the prostate (TURP) as a standard treatment modality in regards to subjective symptom relief and objective improvements in urinary flow (EAU 2017; McVary 2011), but this procedure is also associated with significant morbidity and long-term complications, including haematuria requiring blood transfusion, urethral stricture, recurrent urinary tract infection, and urinary incontinence. Moreover, men may experience ejaculatory (65%) and erectile dysfunction (10%) related to TURP (Roehrborn 2003). Furthermore, BPH is a disease common in elderly men who have an increased risk of complications for general anaesthesia and the surgery itself (Dunphy 2015; Yoo 2012). Nowadays, other minimally invasive surgeries using electrode, laser, transurethral thermal ablation of the prostate (needle ablation, microwave therapy, and radiofrequency ablative techniques), and mechanical stents have been developed as alternatives to TURP (EAU 2017; McVary 2011). While new laser-based procedures have demonstrated a decrease in short-term complications, such as bleeding, they also have similar adverse effects on sexual function when compared with TURP (NICE 2015). Thermal ablation therapies may have fewer serious adverse events than TURP but can be associated with long periods of irritative symptoms and the need of urinary catheterization (EAU 2017; McVary 2011). In addition, most men considering...
surgical intervention do so in the expectation of this providing a more definitive therapy for their LUTS thereby precluding the need for additional medical or surgical therapy. Given relatively high rates of reoperation or continued use of medical therapy after surgical treatment (or both), there are concerns about the durability of newly launched minimal invasive surgeries (NICE 2015; Jones 2015).

Description of the intervention

A less invasive surgical intervention known as the prostatic urethral lift (PUL) has recently become available. The US Food and Drug Administration approved PUL in September 2013 and the National Institute for Health and Care Excellence in the UK in September 2015 (McNicholas 2016). As the PUL procedure can be performed under local anaesthesia with oral or intravenous sedation, and also be performed in men with blood clotting disorders or men receiving anticoagulant therapy, it is more suitable for men at high risk of general anaesthesia (Chin 2012; Woo 2012). Typical inclusion criteria of PUL are a prostate volume between 20 mL and 70 mL, IPSS of 12 or greater, a measured $Q_{\text{max}}$ of 15 mL/second or less, and PVR of less than 350 mL (McNicholas 2016). The PUL system consists of two single-use components (delivery device and an implant). The delivery device consists of a hand-held pistol grip to which a needle-shaped probe is attached. Each PUL implant consists of a super-elastic nitinol capsular tab, a polyethylene terephthalate monofilament, and a stainless-steel urethral end piece. The surgeon inserts the probe into the urethra until it reaches the prostatic urethra (the widest part of the prostatic urethra); a fine needle at the end of the probe deploys and secures an implant in a lobe of the prostate (McNicholas 2016). One end of the implant is anchored in the urethra and the other is attached to the firm outer surface of the prostatic capsule, so pulling the prostatic lobe away from the urethra. This is repeated on the other lobe of the prostate. Systematically, four implants for PUL are delivered, two each the right and left lateral lobes of the prostate (at the 2 and 10 o’clock position, distally from approximately 1.5 cm distal to the bladder neck). PUL is unable to treat a median lobe of the prostate which causes obstructive intravesical protrusion of prostate (McNicholas 2016).

Adverse events of the intervention

Mild adverse events, such as transient dysuria and haematuria are commonly reported with PUL (Chin 2012; Woo 2012). Incontinence was less prevalent with PUL (5%) compared with TURP (11%) (NICE 2015). However, reoperation rates were higher with the PUL (8%) than with TURP (6%) (NICE 2015). In one feasibility study, implant encrustation occurred when PUL implants are placed too close to the bladder and exposed to static urine (Chin 2012; Woo 2012).

How the intervention might work

The fundamental idea of PUL is the separation and distraction of the enlarged prostatic tissue by a series of implants. The PUL system uses adjustable, permanent implants to hold excess prostatic tissue out of the way and thereby open the narrowed urethra without cutting or removing enlarged prostatic tissue (McNicholas 2016). These implants are shaped as a double-ended hook, and aim to increase the opening of the urethra (McNicholas 2016).

Why it is important to do this review

Until now, it is unclear whether PUL actually translates into more clinical benefits and fewer adverse events in clinical practice. While there are existing systematic reviews that compare PUL to other therapies used to treat BPH (Jones 2016; Perera 2015; Sanchez-Gomez 2015), these reviews merely pooled efficacy measurements, such as IPSS, $Q_{\text{max}}$, and PVR from randomized controlled trials (RCTs) or non-RCTs, without discussing the safety of the intervention or assessing the certainty of evidence. No systematic review to date has used the same rigorous methodology as a Cochrane Review, which includes the application of the GRADE approach and its focus on patient-important outcomes (Guyatt 2008). In contemporary practice, with the availability of numerous minimally invasive procedures to treat BPH, the findings of this Cochrane Review are expected to be relevant to policymakers, healthcare providers, and patients.

OBJECTIVES

To assess the effects of PUL for the treatment of LUTS in men with BPH.

METHODS

Criteria for considering studies for this review

Types of studies

We included parallel-group RCTs and cluster-RCTs. We excluded cross-over trials, as these study designs are not relevant in this setting. If we had only found RCTs that provided low-certainty evidence for a given outcome and comparison, we planned to include non-RCTs, such as cohort and cross-sectional studies with concurrent comparison groups, as a source of complementary, sequential, or replacement evidence for RCTs (Schünemann 2013). We planned to exclude single-armed studies. We included studies regardless of their publication status or language of publication.
Types of participants
We defined the eligible patient population as men over the age of 40 years with a prostate volume of 20 mL or greater (as assessed by digital rectal examination, ultrasound or cross-sectional imaging, or both), with LUTS as determined by an IPSS of eight or over, and a \(Q_{\text{max}}\) of less than 15 mL/second, as measured by non-invasive uroflowmetry, or invasive pressure flow studies, or both (Dunphy 2015; EAU 2017; McNicholas 2016; McVary 2011). The age limitation was based on the observation that the prevalence of BPH increases in middle-aged and older men, and is infrequent in younger men (Barry 1997; Egan 2016; EAU 2017).

We planned to exclude trials of men with active urinary tract infection; bacterial prostatitis; chronic renal failure; untreated bladder calculi or large diverticula; prostate cancer; urethral stricture disease; and prior prostate, bladder neck, or urethral surgery. We also planned to exclude studies of men with other conditions that affect urinary symptoms, such as neurogenic bladder due to spinal cord injury, multiple sclerosis, or central nervous system disease.

Types of interventions
We compared the experimental and comparator interventions for the following outcomes. Concomitant interventions had to be the same in the experimental and comparator groups to establish fair comparisons.

Experimental interventions
- PUL.

Comparator interventions
- Sham control (or no intervention).
- TURP (monopolar or bipolar).
- Laser ablations of the prostate (e.g. photoselective vaporization of the prostate).
- Laser enucleations of the prostate (e.g. holmium laser enucleations of the prostate).
- Other minimally invasive therapies (e.g. transurethral incision of the prostate, transurethral thermal ablation of the prostate (needle ablation, microwave therapy, and radiofrequency ablative techniques), prostate stent, and prostatic arterial embolization).
- Simple prostatectomy (e.g. open, laparoscopic, and robotic-assisted prostatectomy).

Comparisons
- PUL versus sham control (or no intervention).
- PUL versus TURP.
- PUL versus laser ablations of the prostate.
- PUL versus laser enucleations of the prostate.
- PUL versus other minimally invasive therapies.
- PUL versus simple prostatectomy.

Types of outcome measures
We did not use the measurement of the outcomes assessed in this review as an eligibility criterion.

Primary outcomes
- Urological symptom scores.
- Quality of life.
- Major adverse events.

Secondary outcomes
- Retreatment.
- Erectile function.
- Ejaculatory function.
- Minor adverse events.
- Acute urinary retention.
- Indwelling urinary catheter.
- Hospital stay.

Method and timing of outcome measurement
We considered clinically important differences for all outcomes as the basis for rating the certainty of the evidence for imprecision in the ‘Summary of findings’ tables (Jaeschke 1989; Johnston 2013).

Urological symptom scores
- Mean change measured as IPSS (also known as American Urological Association Symptom Index).
  - We considered an improvement of the IPSS score of three points as the minimal clinically important difference (MCID) to assess efficacy and comparative effectiveness (Barry 1995).

Quality of life
- Mean change measured as IPSS-quality of life.
  - No formal threshold was established for the IPSS-quality of life. We used an MCID of 0.5 to assess efficacy and comparative effectiveness (Brasure 2016; Rees 2015).

Major adverse events
- For example, postoperative haemorrhage requiring admission or intervention.
  - We used the Clavien-Dindo classification system to assess surgical complications (Dindo 2004), and categorized grade III, IV, and V complications as major (Grazzke 2017). We judged the adverse events by severity using the available information described in Roehrborn 2013.
  - Based on Guyatt 2011a, we considered a 25% relative change as threshold for a clinically important difference.
Retreatment

- Events requiring other surgical treatment modalities (e.g., TURP) after intervention.
- Based on Guyatt 2011a, we considered a 25% relative change as threshold for a clinically important difference.

Erectile function

- Mean change, measured as total score of International Index of Erectile Function (IIEF)-5 questionnaire (also known as Sexual Health Inventory for Men) (Rosen 1997).
- We considered a difference in IIEF-5 over five points as MCID (Spaliviero 2010).

Ejaculatory function

- Mean change, measured as Male Sexual Health Questionnaire for Ejaculatory Dysfunction (MSHQ-EjD); (Rosen 2007).
- We used an MCID of 25% improvement from baseline in MSHQ-EjD for ejaculatory function (Nickel 2015).

Minor adverse events

- For example, postoperative fever or pain requiring medication.
- We used the Clavien-Dindo classification system to assess surgical complications (Dindo 2004), and categorized grade I and II complications as minor (Gratzke 2017). For one of the included studies (Roehrborn 2013), we graded the adverse events as described above.
- Based on Guyatt 2011a, we considered a 25% relative change as threshold for a clinically important difference.

Acute urinary retention

- Events requiring catheterization after intervention.
- Based on Guyatt 2011a, we considered a 25% relative change as threshold for a clinically important difference.

Indwelling urinary catheter

- Proportion of participants with indwelling catheter at postoperative 24 hours.
- Based on Guyatt 2011a, we considered a 25% relative change as threshold for a clinically important difference.

Hospital stay

- Measured in days from admission to discharge.
- We considered a one-day difference in mean hospital stay as the threshold for a clinically important difference.

We considered outcomes measured up to and including 12 months after randomization as short-term and later than 12 months as long-term for urological symptom scores, quality of life, major adverse events, retreatment, erectile function, ejaculatory function, minor adverse events, and acute urinary retention. We assessed indwelling urinary catheter and hospital stay as short-term only.

Main outcomes for ‘Summary of findings’ tables

We presented ‘Summary of findings’ tables reporting the following outcomes listed according to priority.

- Urological symptom scores.
- Quality of life.
- Major adverse events.
- Retreatment.
- Erectile function.
- Ejaculatory function.

Search methods for identification of studies

We performed a comprehensive search with no restrictions on the language of publication or publication status.

Electronic searches

We initially searched the following sources from inception of each database to 26 May 2017. The date of last search of all databases was 31 January 2019 (Appendix 1).

  - Cochrane Database of Systematic Reviews.
  - Cochrane Central Register of Controlled Trials.
  - Database of Abstracts of Reviews of Effects.
  - Health Technology Assessment Database.
- MEDLINE via Ovid (from 1946).
- Embase via Elsevier (from 1947).
- LILACS (Latin American and the Caribbean Health Sciences Literature; www.bireme.br/; from 1982).
- Scopus (from 1966).
- Web of Science (from 1900).
- Google Scholar

We also searched the following.

- ClinicalTrials.gov (www.clinicaltrials.gov/).
- World Health Organization (WHO) International Clinical Trials Registry Platform search portal (apps.who.int/trialsearch/).
- Grey literature repository from the current Grey Literature Report (www.greylit.org/).

Searching other resources

We tried to identify other potentially eligible trials or ancillary publications by searching the reference lists of retrieved included trials, reviews, meta-analyses, and health technology assessment
reports. We also contacted study authors of included trials to identify any further studies that we may have missed. We contacted drug/device manufacturers for ongoing or unpublished trials. We searched abstract proceedings of relevant meetings of the American Urological Association, European Association of Urology, and International Continence Society for 2015 to 2017 from initial date of search and then updated the search for the most recent year (2018) for unpublished studies.

Data collection and analysis

Selection of studies
We used EndNote 2016 reference management software to identify and remove potential duplicate records. Two review authors (JHJ, BR, or KAM) independently scanned the abstracts, titles, or both to determine which studies should be assessed further using Covidence 2013 software. Two review authors (JHJ, BR, or KAM) investigated all potentially relevant records as full text, mapped records to studies, and classified studies as included studies, excluded studies, studies awaiting classification, or ongoing studies in accordance with the criteria for each provided in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011a). We resolved any discrepancies through consensus or recourse to a third review author (PD). We documented reasons for exclusion the Characteristics of excluded studies table. We presented an adapted PRISMA flow diagram showing the process of study selection (Liberati 2009).

Data extraction and management
We developed a dedicated data abstraction form that we pilot tested ahead of time. For studies that fulfilled inclusion criteria, two review authors (JH and BR) independently abstracted the following information, which we provided in the Characteristics of included studies table.

- Study design.
- Study dates.
- Study settings and country.
- Participant inclusion and exclusion criteria (e.g. age, baseline IPSS).
- Participant details, baseline demographics (e.g. age, prostate size, IPSS).
- Number of participants by study and by study arm.
- Details of relevant experimental intervention, such as delivery devices (e.g. size of cystoscope and needle to delivery implants) for PUL and comparator intervention (e.g. monopolar versus bipolar energy, type of laser).
- Definitions of relevant outcomes, and method (e.g. type of instrument, such as IPSS) and timing of outcome measurement (e.g. in months) as well as any relevant subgroups (e.g. based on age, prostate volume, severity of LUTS).
- Study funding sources.
- Declarations of interest by primary investigators.

We extracted outcome data relevant to this Cochrane Review as needed for calculation of summary statistics and measures of variance. For dichotomous outcomes, we obtained numbers of events and totals for population in a 2 × 2 table, as well as summary statistics with corresponding measures of variance. For continuous outcomes, we obtained means and standard deviations or data necessary to calculate this information.

We resolved any disagreements by discussion, or, if required, by consultation with a third review author (PD). We provided information, including trial identifier, about potentially relevant studies in the Characteristics of studies awaiting classification or Characteristics of ongoing studies tables. We contacted authors of included studies to obtain key missing data as needed.

Dealing with duplicate and companion publications
In the event of duplicate publications, companion documents, or multiple reports of a primary study, we maximized yield of information by mapping all publications to unique studies and collating all available data. We used the most complete data set aggregated across all known publications. In case of doubt, we gave priority to the publication reporting the longest follow-up associated with our primary or secondary outcomes.

Assessment of risk of bias in included studies
Two review authors (JH and BR) independently assessed the risk of bias of each included study. We resolved disagreements by consensus, or by consultation with a third review author (PD). We present a ‘Risk of bias’ summary figure to illustrate these findings. We further summarized the risk of bias across domains for each outcome in each included study, as well as across studies and domains for each outcome in accordance with the approach for summary assessments of the risk of bias presented in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011b; Sterne 2016).

Assessment of risk of bias in randomized controlled trials
We assessed risk of bias using Cochrane’s ‘Risk of bias’ assessment tool (Higgins 2011b). We assessed the following domains.

- Random sequence generation (selection bias).
- Allocation concealment (selection bias).
- Blinding of participants and personnel (performance bias).
- Blinding of outcome assessment (detection bias).
- Incomplete outcome data (attrition bias).
- Selective reporting (reporting bias).
- Other sources of bias.
We judged risk of bias domains as 'low risk', 'high risk', or 'unclear risk' and evaluated individual bias items as described in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011b).

For selection bias (random sequence generation and allocation concealment), we evaluated risk of bias at a trial level.

For performance bias (blinding of participants and personnel), we considered all outcomes similarly susceptible to performance bias.

For detection bias (blinding of outcome assessment), we grouped outcomes as susceptible to detection bias (subjective) or not susceptible to detection bias (objective) outcomes.

We defined the following endpoints as subjective outcomes.
- Urological symptom scores.
- Quality of life.
- Major adverse events.
- Erectile function.
- Ejaculatory function.
- Minor adverse events.

We defined the following endpoints as objective outcomes.
- Retreatment.
- Acute urinary retention.
- Indwelling urinary catheter.
- Hospital stay.

We assessed attrition bias (incomplete outcome data) on an outcome-specific basis, and presented the judgement for each outcome separately when reporting our findings in the 'Risk of bias' tables.

For reporting bias (selective reporting), we evaluated risk of bias at a trial level.

Assessment of risk of bias in non-randomized controlled trials
We planned to assess risk of bias in non-RCTs with ROBINS-I: a tool for assessing risk of bias in non-randomized studies of interventions (Sterne 2016).
- Bias due to confounding.
- Bias in selection of participants into the study.
- Bias in classification of interventions.
- Bias due to deviations from intended interventions.
- Bias due to missing data.
- Bias in measurement of outcomes.
- Bias in selection of the reported result.

We planned to judge risk of bias domains as 'low risk', 'moderate risk', 'serious risk', 'critical risk', or 'no information' and evaluate individual bias items as described in Sterne 2016.

Measures of treatment effect
We expressed dichotomous data as risk ratios (RRs) with 95% confidence interval (CIs). We expressed continuous data as mean differences (MDs) with 95% CIs.

Unit of analysis issues
The unit of analysis was the individual participant. For cluster-trials, or trials with more than two intervention groups, we planned to incorporate these study designs in meta-analysis in accordance with guidance provided in the Cochrane Handbook for Systematic Reviews of Interventions (Higgins 2011c).

Dealing with missing data
We obtained missing data from study authors and performed intention-to-treat analyses if data were available. We investigated attrition rates (e.g. dropouts, losses to follow-up, and withdrawals), and critically appraised issues of missing data. We did not impute missing data.

Assessment of heterogeneity
We planned to identify heterogeneity (inconsistency) through visual inspection of the forest plots to assess the amount of overlap of CIs, and the I² statistic, which quantified inconsistency across studies to assess the impact of heterogeneity on the meta-analysis (Higgins 2002; Higgins 2003). We planned to interpret the I² statistic as follows (Deeks 2011).
- 0% to 40%: may not be important.
- 30% to 60%: may indicate moderate heterogeneity.
- 50% to 90%: may indicate substantial heterogeneity.
- 75% to 100%: considerable heterogeneity.

Assessment of reporting biases
We tried to obtain study protocols to assess for selective outcome reporting.
As we included only one study for each comparison, we could not use funnel plots to assess small-study effects.

Data synthesis
Given that we included only one study for each comparison, we only reported single study data using Review Manager 5 software (Review Manager 2014).

Subgroup analysis and investigation of heterogeneity
We expected the following characteristics to introduce clinical heterogeneity, and planned to carry out subgroup analyses with investigation of interactions.
- Patient age (less than 65 years versus 65 years and older).
- Prostate volume (40 mL or less versus greater than 40 mL).
- Severity of LUTS based on IPSS (score 19 (moderately symptomatic) or less versus greater than 19 (severely symptomatic)).

These subgroup analyses are based on the following observations.
• Age is a well-known risk factor of BPH surgery. Older people have a higher rate of postoperative complications compared with younger people (Bhojani 2014; Pariser 2015). The age cut-off was based on the WHO definition of old age (WHO 2002).
• The outcomes and complications of minimally invasive procedures, such as TURP, correlate with prostate volume (Reich 2008). The prostate volume cut-off greater than 40 mL was based on this being the most commonly used threshold to distinguish 'small' from 'large' for the indication of treatment with a 5-alpha reductase inhibitor (EAU 2017).
• The relationship between changes in IPSS scores and patient global ratings of improvement is influenced by the baseline scores (Barry 1995).

We planned to perform subgroup analyses limited to the primary outcomes.

Sensitivity analysis
We planned to perform sensitivity analyses limited to the primary outcomes to explore the influence of the following factors (when applicable) on effect sizes.
• Restricting the analysis in RCTs by taking into account risk of bias, by excluding studies at 'high risk' or 'unclear risk'.

'Summary of findings' tables
We presented the overall certainty of the evidence for each outcome according to the GRADE approach (Guyatt 2008). For each comparison, two review authors (JHJ and BR) independently rated the certainty of evidence for each outcome as 'high', 'moderate', 'low', or 'very low' using GRADEpro GDT 2015. We resolved any discrepancies by consensus, or, if needed, by arbitration by a third review author (PD). For each comparison, we presented a summary of the evidence for the main outcomes in a 'Summary of findings' table, which provides key information about the best estimate of the magnitude of the effect in relative terms and absolute differences for each relevant comparison of alternative management strategies; numbers of participants and studies addressing each important outcome; and the rating of the overall confidence in effect estimates for each outcome (Guyatt 2011b; Schünemann 2011a).

For RCTs, we took into account five criteria related to internal validity (risk of bias, inconsistency, imprecision, and publication bias), and external validity (such as directness) of results for downgrading the certainty of evidence for a specific outcome (Schünemann 2011b). For non-RCTs, we planned to take into account three criteria for upgrading the certainty of evidence (large magnitude of effects, all plausible confounding that would reduce a demonstrated effect or suggest a spurious effect when results show no effect, and dose-response gradient) (Schünemann 2011b).

RESULTS

Description of studies

Results of the search
We identified 657 records through electronic database searching, including 10 records in trials registers. We found no records in the grey literature repository, and reference lists of retrieved included trials and reviews. After removal of duplicates, we screened the titles and abstracts of 283 records, and excluded 252 records. We screened 31 full-text articles and excluded one record due to wrong study design. We found one study awaiting classification (two records). We included two studies (28 records) in the review. The flow of literature through the assessment process is shown in the PRISMA flowchart (Figure 1).
Figure 1. PRISMA flow diagram.

657 records identified through database searching

0 additional records identified through other sources: grey literature repository

283 records after duplicates removed

283 records screened

252 records excluded

31 full-text articles assessed for eligibility

1 full-text article excluded, with reason:
- Wrong study design (1 record)

2 studies awaiting classification (2 records)

2 studies (28 records) included in qualitative synthesis

Included studies
Details of included studies are presented elsewhere (Characteristics of included studies; Table 1; Table 2). In brief,
- Roehrborn 2013 randomized 206 men of 50 years of age or older with an IPSS greater than 12, $Q_{\text{max}}$ 12 mL/second or less, and prostate volume of 30 cm$^3$ to 80 cm$^3$ to PUL versus sham surgery.
- Gratzke 2017 randomized 91 men of 50 years of age or older with an IPSS greater than 12, $Q_{\text{max}}$ 15 mL/second or less, and prostate volume 60 cm$^3$ or less to PUL versus TURP.

Source of data
We identified the two published full-text studies through our electronic database search (Gratzke 2017; Roehrborn 2013). Both trials were published in English. We attempted to contact the corresponding authors of the included trials to obtain additional information on study methodology and results, and received reply from Roehrborn 2013 (Appendix 2).

Study design and settings
Both trials were multicentre, parallel, RCTs across Europe, US, Canada, and Australia. One study was reported as “open-label” in the protocol (Gratzke 2017), but the other was unclear for the blinding (single blinded in protocol, but double blinded in full-text publication (Roehrborn 2013). The studies were performed from 2011 to 2013.
Participants
We included 297 randomized participants (PUL 185, sham 66, TURP 46). Out of 297 participants, 275 were included in the efficacy (urological symptom scores: PUL 177, sham 66, TURP 32) and 285 were included in safety (adverse events: PUL 185, sham 66, TURP 35) analysis. The mean age was 65.6 years, mean IPSS was 22.7, and mean Q\textsubscript{max} was 8.9 mL/second. Mean prostate volume was 42.2 mL.

Both studies included participants with LUTS of a total IPSS more than 12 and prostate volume less than 80 mL (Gratzke 2017: less than 60 mL, Roehrborn 2013: 30 mL to 80 mL). One study used a Q\textsubscript{max} of 15 mL/second or less (Gratzke 2017) and one study used 15 mL/second (Roehrborn 2013) as an inclusion criterion. Major exclusion criteria included active urinary tract infection, urinary retention, raised PSA level suspicious of prostate cancer, history of prior prostate-related surgery such as TURP or laser procedure, and other medical conditions or medical comorbidities that represented relative or absolute contraindications for TURP or PUL.

Intervention(s) and comparator(s)
Both studies used permanent intraprostatic UroLift implants (NeoTract, Inc., Pleasanton, CA) as interventions. Roehrborn 2013 used sham surgery and Gratzke 2017 used TURP as a comparator. After rigid cystoscopy was performed, the implant delivery device was inserted into the cystoscopic sheath. Under cystoscopic visualization, PUL implants were permanently implanted to retract obstructing lateral lobes and widen the urethral lumen (Gratzke 2017; McNicholas 2016; Roehrborn 2013). For sham procedures, after a rigid cystoscopy was performed, the surgeon requested the devices which were opened but not deployed. A device was not inserted, but was deployed four times outside the patients' body to simulate the device sounds (Roehrborn 2013). TURP procedures were performed in accordance with normal standards and practices of participating centres with no other details being provided about the devices being used by Gratzke 2017. Roehrborn 2013 conducted almost all PUL procedures under local anaesthesia. Gratzke 2017 appeared to have performed PUL procedures under general or spinal anaesthesia.

While Roehrborn 2013 reported five-year follow-up data for the PUL group as an extended open-label study, we, in accordance with our published protocol, only used three-month follow-up data for which there was a concurrent comparison groups (PUL and sham). The follow-up duration of Gratzke 2017 was 24 months.

Comparisons
The included two studies compared PUL to sham (Roehrborn 2013) or TURP (Gratzke 2017). We found no studies comparing PUL to laser ablations of the prostate, laser enucleations of the prostate, other minimally invasive therapies, or simple prostatectomy.

Outcomes
We identified reporting of all primary outcomes in each of the included studies for both comparisons. In addition, all secondary outcomes were reported in each of the included studies except for indwelling catheter requirements.

Funding sources and conflicts of interest
Both included studies were supported by the same medical device company and also reported the authors having financial relationships with the same as well as other pharmaceutical or medical device companies, or both.

Excluded studies
We excluded one abstract that was a single armed and posthoc analysis of the included study (Gratzke 2018). See Characteristics of excluded studies table.

Studies awaiting classification and ongoing trials
We found one study awaiting classification that appeared to meet inclusion criteria. Details of this study are presented in the Characteristics of studies awaiting classification table. In brief, this is a non-randomized prospective study comparing a men with similar symptoms of LUTS undergoing either PUL or prostatic arterial embolization. The study has yet to begin accrual at the time of completion of this review. We plan to include its findings in future updates.

Risk of bias in included studies
See Figure 2; Figure 3.
Figure 2. Risk of bias graph: review authors' judgements about each risk of bias item presented as percentages across all included studies.

Legend: 
- Green: Low risk of bias
- Yellow: Unclear risk of bias
- Red: High risk of bias
### Allocation

**Random sequence generation**
We rated both studies at low risk of bias since they used appropriate methods of random sequence generation.

**Allocation concealment**
We rated both studies at low risk of bias since both indicated appropriate concealment of participant allocation.

### Blinding

**Roehrborn 2013** reported that ‘double blinding’ was maintained for three months after intervention, but there are concerns whether this was the case given that the study protocol referred to a single-blinded design. However, the author clarified blinding of participants and outcome assessor.

**Blinding of participants and personnel**
We rated both studies at high risk of bias due to a lack of blinding (Gratzke 2017: non-blinded; Roehrborn 2013: non-blinded for
Blinding of outcome assessment

- Subjective outcomes (urological symptom scores, quality of life, major adverse events, erectile function, ejaculatory function, and minor adverse events): we rated one study at low risk of bias based on author's response (Roehrborn 2013), but we judged the other at high risk of bias (Gratzke 2017).
- Objective outcomes (retreatment, acute urinary retention, indwelling urinary catheter, and hospital stay): we rated both studies at low risk of bias for these outcomes because these outcomes are unlikely to be affected by lack of blinding.

Incomplete outcome data

While Roehrborn 2013 only reported short-term outcomes (up to 12 months' follow-up), Gratzke 2017 reported both short- and long-term (longer than 12 months' follow-up) outcome data. We rated the risk of bias separately for all outcomes in Gratzke 2017 according to the timing of outcome measurement (short term and long term) but these judgements were identical with the exception of major adverse events.
- Urological symptom scores and quality of life: while rating one study at low risk of bias (Roehrborn 2013), we judged the other at unclear risk of bias (Gratzke 2017).
- Major and minor adverse events: we rated both studies at low risk of bias.
- Retreatment: we rated both studies at low risk of bias.
- Erectile function: we rated one study at low risk of bias (Roehrborn 2013), and the other at high risk of bias (Gratzke 2017).
- Ejaculatory function: we rated both studies at high risk of bias.
- Acute urinary retention: we rated both studies at low risk of bias.
- Indwelling urinary catheter: we rated both studies at unclear risk of bias due to lack of information.
- Hospital stay: we rated both studies at low risk of bias.

Selective reporting

We rated both studies at low risk of bias given the availability of registration protocols and concordance of planned and actual analyses for all of our predefined outcomes.

Other potential sources of bias

We rated both studies at low risk of bias; no other sources of bias were identified.

Effects of interventions

See: Summary of findings for the main comparison PUL compared to TURP for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia (short term); Summary of findings 2 PUL compared to TURP for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia (long term); Summary of findings 3 PUL compared to sham for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia (short term)

Prostatic urethral lift versus sham (short term)

We found one study comparing PUL versus sham with short-term follow-up which randomized 206 participants (PUL 140, sham 66) (Roehrborn 2013). All randomized participants were included in the analysis for primary and secondary outcomes except for the outcomes of erectile function (197 participants; PUL 132, sham 65), ejaculatory function (144 participants; PUL 94, sham 50), and hospital stay (201 participants; PUL 137, sham 64).

There were no studies with long-term follow-up. The results are presented in a summary of findings table (Summary of findings 3).

Primary outcomes

1. Urological symptom scores

PUL may lead to a clinically important reduction in urological symptom scores (MD -5.20, 95% CI -7.44 to -2.96). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 1.1).

2. Quality of life

PUL likely results in similar improvement in quality of life (MD -1.20, 95% CI -1.67 to -0.73) as sham surgery. We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 1.2).

3. Major adverse events

We are very uncertain about the effects of PUL on major adverse events (RR 3.30, 95% CI 0.41 to 26.28). We rated the certainty of the evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 1.3).
Secondary outcomes

1. Retreatment
There were no retreatments in either study group at three months’ follow-up. We rated the certainty of the evidence as low, downgrading for study limitations and imprecision.

2. Erectile function
PUL likely results in little to no difference in erectile function (MD -1.40, 95% CI -3.24 to 0.44). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 1.5).

3. Ejaculatory function
PUL likely results in little to no difference in ejaculatory function (MD 0.50, 95% CI -0.38 to 1.38). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 1.4).

4. Minor adverse events
PUL likely increases minor adverse events (RR 1.69, 95% CI 1.33 to 2.16). PUL would result in 355 more minor adverse events per 1000 men (95% CI 170 more to 598 more). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 1.6).

5. Acute urinary retention
We are very uncertain about the effects of PUL on acute urinary retention (RR 0.47, 95% CI 0.03 to 7.42). We rated the certainty of the evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 1.7).

6. Indwelling urinary catheter
The study did not report the need for an indwelling urinary catheter.

7. Hospital stay
PUL likely results in little to no difference in hospital stay (MD 0.03, 95% CI -0.09 to 0.15). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 1.8).

Subgroup and sensitivity analysis
We were unable to perform any predefined secondary analyses because there were no relevant data.

Prostatic urethral lift versus transurethral resection of prostate (short term)
One trial compared PUL versus TURP (Gratzke 2017). We included 72 participants (PUL 40, TURP 32) in the analysis for urological symptom scores and quality of life; 79 participants (PUL 44, TURP 35) in the analysis for major adverse events, retreatment, minor adverse events, acute urinary retention, indwelling urinary catheter, and hospital stay; and 59 participants (PUL 32, TURP 27) in the analysis for erectile and ejaculatory function. The results are presented in a summary of findings table (Summary of findings for the main comparison).

Primary outcomes

1. Urological symptom scores
PUL may result in a substantially lesser improvement in urological symptom scores compared with TURP (MD 4.50, 95% CI 1.10 to 7.90; low-certainty evidence). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 2.1).

2. Quality of life
PUL may result in little to no difference in quality of life (MD 0.30, 95% CI -0.49 to 1.09) compared to TURP. We rated the certainty of the evidence as low, downgrading for study limitations (Analysis 2.2).

3. Major adverse events
We are very uncertain about the effects of PUL on major adverse events (RR 0.64, 95% CI 0.18 to 2.19). We rated the certainty of the evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 2.3).

Secondary outcomes

1. Retreatment
We are very uncertain about the effects of PUL on retreatment (RR 1.19, 95% CI 0.21 to 6.75). We rated the certainty of the
evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 2.4).

2. Erectile function
PUL likely results in little to no difference in erectile function (MD 0.80, 95% CI -1.50 to 3.10). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 2.5).

3. Ejaculatory function
PUL likely preserves ejaculatory function to a similar extent as TURP (MD 5.00, 95% CI 3.08 to 6.92). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 2.6).

4. Minor adverse events
PUL may result in slightly fewer minor adverse events compared with TURP (RR 0.88, 95% CI 0.70 to 1.09). PUL would result in 103 fewer minor adverse events per 1000 men (95% CI 257 fewer to 77 more). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 2.7).

5. Acute urinary retention
We are very uncertain about the effects of PUL on acute urinary retention, which may be much higher or lower (RR 7.20, 95% CI 0.40 to 129.38). We rated the certainty of the evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 2.8).

6. Indwelling urinary catheter
PUL may reduce the need for an indwelling urinary catheter (RR 0.46, 95% CI 0.25 to 0.84). PUL would result in 293 fewer indwelling urinary catheters per 1000 men (95% CI 87 fewer to 407 fewer). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 2.9).

7. Hospital stay
PUL may result in a small reduction in hospital stay, but this may not represent a clinically important difference (MD -0.90, 95% CI -1.32 to -0.48). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 2.10).

Subgroup and sensitivity analysis
We were unable to perform secondary analyses because there were no relevant data or too few data in the included studies.

Prostatic urethral lift versus transurethral resection of prostate (long term)
We included one trial for long-term follow-up of PUL versus TURP (Gratzke 2017). We included 69 participants (PUL 37, TURP 32) in the analysis for urological symptom scores and quality of life; 79 participants (PUL 44, TURP 35) in the analysis for retreatment; 57 participants in the analysis for erectile (PUL 29, TURP 28); 56 participants in the analysis for ejaculatory function (PUL 29, TURP 27); and 80 participants (PUL 45, TURP 35) in the analysis for minor adverse events. The results are presented in a summary of findings table (Summary of findings 2).

Primary outcomes

1. Urological symptom scores
PUL may reduce urological symptom scores less than TURP (MD 6.10, 95% CI 2.16 to 10.04). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 3.1).

2. Quality of life
PUL may result in little to no difference in quality of life (MD 0.80, 95% CI 0.00 to 1.60). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 3.2).

3. Major adverse events
The study did not report major adverse events.

Secondary outcomes

1. Retreatment
We are very uncertain about the effects of PUL on retreatment (RR 2.39, 95% CI 0.51 to 11.10). We rated the certainty of the evidence as very low, downgrading for study limitations and very serious imprecision (Analysis 3.3).
2. Erectile function
PUL likely results in little to no difference in erectile function (MD 1.60, 95% CI -0.80 to 4.00). We rated the certainty of the evidence as moderate, downgrading for study limitations (Analysis 3.4).

3. Ejaculatory function
PUL may preserve ejaculatory function to a greater extent than TURP (MD 4.30, 95% CI 2.17 to 6.43). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 3.5).

4. Minor adverse events
PUL may result in slightly fewer minor adverse events (RR 0.92, 95% CI 0.72 to 1.17). PUL would result in 64 fewer minor adverse events per 1000 men (95% CI 224 fewer to 136 more). We rated the certainty of the evidence as low, downgrading for study limitations and imprecision (Analysis 3.6).

5. Acute urinary retention
The study did not report acute urinary retention.

6. Indwelling urinary catheter
The study did not report the need for an indwelling urinary catheter.

7. Hospital stay
The study did not report hospital stay.

Subgroup and sensitivity analysis
We were unable to perform secondary analyses because there were no relevant data.
## ADDITIONAL SUMMARY OF FINDINGS

### PUL compared to TURP for the treatment of lower urinary tract symptoms in men with benign prostatic hyperplasia (long term)

**Participants:** men with BPH  
**Setting:** multicentre in Europe  
**Intervention:** PUL  
**Control:** TURP

**GRADE Working Group grades of evidence**

High certainty: we are very confident that the true effect lies close to that of the estimate of the effect.

Moderate certainty: we are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.

Low certainty: our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.

Very low certainty: we have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of effect.

α Downgraded one level for study limitations: high risk of performance.
β Downgraded one level for imprecision: confidence interval crossed assumed threshold of clinically important difference.
γ Downgraded two levels for imprecision: wide confidence interval crossed assumed threshold of clinically important difference.
δ Downgraded one level for imprecision: very rare event.
ε Downgraded one level for study limitations: high risk of performance or attrition bias, or both.
η Minimal clinically important difference: 25% improvement (greater than 2 points) from the baseline (PUL: 8.7; sham: 8.8).
DISCUSSION

Summary of main results
We included two studies with 297 randomized participants comparing PUL to sham or TURP.

Prostatic urethral lift versus sham
Based on one study with comparative data up to three months only, PUL may lead to reduce urological symptoms and likely improves quality of life more than sham surgery. We are very uncertain about the effects of PUL on major adverse events. There were no reported retreatments in either study group. PUL likely results in little to no difference in erectile and ejaculatory function.

Prostatic urethral lift versus transurethral resection of prostate
Short-term, PUL may result in a substantially lesser reduction of urological symptoms than TURP although quality of life may be similar. We are uncertain about the effects of PUL on major adverse events and retreatment rates. While there may be no difference in erectile function, ejaculatory function may be better preserved. Long-term, PUL may also result in a substantially lesser reduction of urological symptoms than TURP although quality of life may be similar. We found no evidence on major adverse events. Also long-term, there may be no difference in erectile function, but ejaculatory function may be better preserved. We were unable to perform any of the predefined secondary analysis for any comparisons. We were unable to assess any other comparisons.

Overall completeness and applicability of evidence
As we found only two trials of two comparisons in this review, this body of evidence has important limitations with regards to applicability to contemporary practice.

• Given the principal mechanism of PUL to compress a prostatic adenoma using a series of implants, men with obstructing median lobes may receive limited therapeutic benefit (McNicholas 2016; Walsh 2017). Roehrborn 2013 excluded men with median lobe obstruction. Gratzke 2017 did not describe the presence of median lobe as an exclusion criteria. Both studies included participants with a prostate volume of less than 80 mL. Both issues limit generalizability with regards to men presenting with LUTS secondary to BPH being considered for surgical management.

• While Gratzke 2017 reported the severity of adverse events based on the Clavien-Dindo classification system, Roehrborn 2013 used a different definition of serious adverse events (e.g. stress incontinence and transfusion were considered as serious adverse events without any definitions being provided). Varied definitions and terminology limited comparability and interpretation.

• When comparing PUL versus sham, the study duration was extremely short (three months) thereby limiting the reported assessment.

• In this review, anaesthesia methods by study varied. While most US-based series were performed under local anaesthesia with or without penile block (Perera 2015), European centres used general or spinal anaesthesia in almost all participants (Gratzke 2017). This appears relevant to a subset of outcomes such as length of hospital stay and acute urinary retention.

Quality of the evidence
We consistently downgraded the certainty of the evidence. The most common reasons for downgrading were study limitations (issues surrounding blinding of participants, personnel, and outcome assessor); given the blinding that is a fundamental safety guard for RCTs, it may result in exaggerated effect size estimates. In addition, we frequently downgraded for imprecision due to wide CIs that crossed the assumed threshold of clinically important differences, usually in the setting of few events. For ejaculatory function, we also downgraded for attrition bias due high rates of participants not included in the analysis (Gratzke 2017: 30.0%, Roehrborn 2013: 30.1%).

Potential biases in the review process
Despite a comprehensive search strategy without any publication or language restrictions, we only found two RCTs. While both included studies used the same criteria on our review outcome measurement, the existing paucity of RCTs may be a source of bias to reaching the conclusion. The small number of studies included in this review were insufficient to generate funnel plots; therefore, the risk of publication bias may have been underestimated. Both included studies were supported by a device company. Therefore, publication bias and favourable reporting, owing to commercial interests with the current method of PUL, cannot be discounted.

Agreements and disagreements with other studies or reviews
We found a few published systematic reviews to elucidate the effects of PUL for the treatment of LUTS in men with BPH (Jones 2016; Magistro 2018; Perera 2015; Sanchez-Gomez 2015). While concluding that PUL was well-tolerated, improved urinary symptoms, and stream, while preserving sexual function, they combined the data from RCTs (Gratzke 2017; Roehrborn 2013) and
non-RCTs (case series or secondary cross-over designed study of Roehrborn 2013). Limited published reports of varying quality in the meta-analysis cause a high degree of heterogeneity. Therefore, we believe that our review was the most rigorous in its methodology; this included a published protocol, a focus on patient-important outcomes, an exhaustive literature search, and an assessment of the certainty of the evidence using GRADE.

In addition, Roehrborn 2013 reported a cumulative retreatment rate of 10.7% at three years and 13.6% at five years for PUL (unblinded single arm follow-up) while Gratzke 2017 reported no difference (6.8% (3/44) of PUL and 5.7% (2/35) of TURP at 1 year). Based on one systematic review and varying by study, 1.5% to 16% of participants underwent TURP after PUL due to insufficient treatment response at the 12-month follow-up (Perera 2015). Meanwhile, one retrospective study of 6430 men undergoing TURP in the US reported the rate of repeated surgical intervention to be only 4% at three years after surgery (Strope 2015). Based on the included trial evidence, we are uncertain about the effects of PUL on retreatment risk due to study limitations and imprecision.

**AUTHORS’ CONCLUSIONS**

**Implications for practice**

PUL may improve urological symptom scores and quality of life similarly as sham surgery short term. Compared to TURP, it is less effective in improving urological symptom scores both short and long term but may offer advantages with regards to the preservation of ejaculatory function. There is considerable uncertainty or lack of evidence (or both) with regards to the risk of major adverse events and retreatment rates over time.

**Implications for research**

We see the following research priorities.

- There appears a critical need for further studies of greater methodological rigor comparing PUL to TURP as well as other treatment modalities such as convective radiofrequency water vapour thermal therapy or holmium laser enucleation. These studies should be of sufficient duration (24 months or longer) and transparently report on treatment-related adverse events and retreatment rates.

- There are few data to help inform which men may be most suitable for PUL based on characteristics such as age, prostate volume, and symptom score. Studies preplanned for subgroup analyses and studies focusing on subsets of men would be helpful.

**ACKNOWLEDGEMENTS**

We are very grateful to Tobias Kohler, Philippe Violette, and Sean McAdams for assistance in the preparation of this review. We thank Cochrane Urology and our contact editor Andrew Shepherd for supporting this review.

## Characteristics of included studies  
**[ordered by study ID]**

### Gratzke 2017

**Methods**
- **Study design:** prospective, randomized, controlled, non-blinded study
- **Setting/country:** 10 centres in Europe (Denmark, the UK, Germany)
- **Dates when study was conducted:** February 2012 to October 2013

### Participants
- **Inclusion criteria:** men aged ≥ 50 years with IPSS > 12, Q\textsubscript{max} ≤ 15 mL/second for 125 mL voided volume, postvoid residual volume < 350 mL, prostate volume ≤ 60 mL on ultrasound, sexually active within 6 months before the index procedure, Sexual Health Inventory for Men score > 6, positive response to MSHQ-EjD (excluding the response “Could not ejaculate”), Incontinence Severity Index score ≤ 4
- **Exclusion criteria:** active urinary tract infection at time of treatment, bacterial prostatitis within 1 year of the index procedure, cystolithiasis within 3 months of the index procedure, obstructive median lobe as assessed via ultrasound and cystoscopy, current urinary retention, urethral conditions that may prevent insertion of a rigid 20 F cystoscope, previous TURP or laser procedure, pelvic surgery or irradiation, PSA ≥ 10 ng/L, history of prostate or bladder cancer, severe cardiac comorbidities, anticoagulants within 3 days of the index procedure (excluding up to 100 mg aspirin (acetylsalicylic acid), other medical condition or comorbidity contraindicative for TURP or PUL, unwilling to report sexual function
- **Total number of participants randomly assigned:** 91
- **Group A (PUL)**
  - Number of all participants randomly assigned: 45
  - Age (mean ± SD): 63 ± 6.8 years
  - Prostate volume (mean ± SD): 38 ± 12 mL
  - PSA (mean ± SD): 2.4 ± 1.8 ng/mL
  - IPSS (mean ± SD): 22 ± 5.7
  - Q\textsubscript{max} (mean ± SD): 9.2 ± 3.5 mL/second
- **Group B (TURP)**
  - Number of all participants randomly assigned: 46
  - Age (mean ± SD): 65 ± 6.4 years
  - Prostate volume (mean ± SD): 41 ± 13 mL
  - PSA (mean ± SD): 2.6 ± 2.1 ng/mL
  - IPSS (mean ± SD): 23 ± 5.9
  - Q\textsubscript{max} (mean ± SD): 9.5 ± 3.2 mL/s

### Interventions
- **Group A:** PUL
  - PUL involved transurethral placement of small, permanent UroLift implants to retract the lateral lobes of the prostate and reduce obstruction. Typically, multiple implants are placed to deobstruct the prostatic urethra. Surgeons’ experiences with PUL varied from 0 to 20 procedures before enrolment
- **Group B:** TURP
  - Licensed urologists trained and experienced in TURP conducted procedures in accordance with their own normal standards and practices
- **Follow-up:** 24 months
Outcomes

**Primary outcomes**
- IPSS
- Sexual Health Inventory for Men
- MSHQ-EjD
- Incontinence Severity Index
- Quality of Recovery visual analogue score

How measured: questionnaires

Time points measured: at baseline, 2 weeks, 1 month, 3 months, 6 months, 1 year, and 2 years

Time points reported: at baseline, 2 weeks, 1 month, 3 months, 6 months, 1 year, and 2 years

**Secondary outcomes**
- PGI-I questionnaire
- SF-12
- Derivative single-index SF-6D utility score
- Jenkins Sleep Questionnaire

How measured: questionnaires

Time points measured: at baseline, 2 weeks, 1 month, 3 months, 6 months, 1 year, and 2 years

Time points reported: PGI-I questionnaire, the SF-12 at 24 months/derivative single-index SF-6D utility score, Jenkins sleep questionnaire at baseline, 2 weeks, 1 month, 3 months, 6 months, 1 year, and 2 years

**Safety outcomes**

How measured: Clavien-Dindo classification of adverse events

Time points measured: not reported

Time points reported: at 1 year

**Subgroup:** none

Funding sources

Drs Speakman, Berges, Sievert, and Sønksen reported grants from NeoTract, Inc

Declarations of interest

Dr Gratzke reported honoraria from Astellas, Lilly, Janssen, and Amgen. Dr Barber reported support from NeoTract, Inc., Olympus, Boston Scientific, and Intuitive Surgical for proctoring and lecturing. Dr Chapple reported personal fees and non-financial support from Allergan, grants, personal fees and non-financial support from Astellas, personal fees and non-financial support from Boston, personal fees and non-financial support from Medtronic, personal fees from Pfizer, personal fees and non-financial support from Recordati, and grants from NeoTract, Inc. during the conduct of the study. Dr Sonksen reported support from NeoTract, Inc. for proctoring and lecturing.

**Roehrborn 2013**

**Methods**

Study design: multicentre randomized blinded trial  
Setting/country: 19 centres in US 14, Canada 2, Australia 3  
Dates when study was conducted: February to December 2011

**Participants**

Inclusion criteria: men aged ≥ 50 years, provided informed consent, had no prior surgical treatment for BPH, and were required to undergo washouts of 2 weeks for alpha-blocker, 3 months for 5α-reductase inhibitor, and 3 days for anticoagulants. Admission to the study required ≥ IPSS 13, $Q_{\text{max}}$ ≤ 12 mL/second with a 125 mL voided volume and a 30- to 80-mL prostate volume  
Exclusion criteria: median lobe obstruction, retention, postvoid residual volume > 250 mL, active infection, PSA > 10 ng/mL (unless negative biopsy), cystolithiasis within 3 months, and bacterial prostatitis within 1 year  
Total number of participants randomly assigned: 206  
**Group A (PUL)**  
- Number of all participants randomly assigned: 140  
- Age (mean ± SD): 67 ± 8.6 years  
- Prostate volume (mean ± SD): 44.5 ± 12.4 mL  
- PSA (mean ± SD): 2.4 ± 2.0 ng/mL  
- IPSS (mean ± SD): 22.2 ± 5.48  
- $Q_{\text{max}}$ (mean ± SD): 8.9 ± 2.2 mL/second  
**Group B (Sham)**  
- Number of all participants randomly assigned: 66  
- Age (mean ± SD): 65 ± 8.0 years  
- Prostate volume (mean ± SD): 40.9 ± 10.8 mL  
- PSA (mean ± SD): 2.1 ± 1.6 ng/mL  
- IPSS: 24.4 ± 5.75  
- $Q_{\text{max}}$ (mean ± SD): 8.8 ± 2.2 mL/second
### Interventions

**Group A:** PUL  
Transprostatic adjustable UroLift implants are permanently implanted to retract obstructing lateral lobes and expand the urethral lumen. After rigid cystoscopy is performed, the implant delivery device is inserted into the 20-F sheath. Under cystoscopic visualization using a 2.9 mm 0-degree lens, the delivery device is angled anterolaterally to compress the obstructive lobe. A 19-gauge needle, housing a monofilament with metallic tab, is then deployed through the prostate lobe. As the needle is retracted, the tab engages the prostate capsule and the monofilament is tensioned. Finally, the urethral end-piece is attached to the monofilament, which is then cut, delivering the in situ-sized implant.

**Group B:** sham  
Conducted with as similar an experience as possible to PUL.

**Follow-up:** 3 months

### Outcomes

**Primary outcome**  
- Reduction in IPSS at 3 months after the PUL procedure was ≥ 25% greater than that of sham  
How measured: IPSS questionnaires  
Time points measured: at baseline, 2 weeks, 1 month, and 3 months  
Time points reported: at baseline, 2 weeks, 1 month, and 3 months

**Secondary outcome**  
- QoL (IPSS-QoL)  
- BPH Impact Index  
- International Index of Erectile Function  
- MSHQ-EjD  
How measured: questionnaires  
Time points measured: at baseline, 2 weeks, 1 month, and 3 months  
Time points reported: at baseline, 2 weeks, 1 month, and 3 months

**Safety outcomes**  
How measured: adverse events  
Time points measured: not reported  
Time points reported: at 3 months

**Subgroup:** none

**Pereira 2018**

| Methods | Study design: retrospective non-randomized parallel assignment (open label)  
Setting/country: single-centre in US  
Dates when study was conducted: not reported  
Participants | Inclusion criteria: men aged ≥ 40 years; willing, able, and mentally competent to provide written informed consent; willing to comply with all study procedures; and be available for the duration of the study with a diagnosis of urinary symptoms from prostatic enlargement refractory to medical therapy for ≥ 6 months (IPSS > 12)  
Exclusion criteria: men with:  
• PAE  
• Active urinary tract infections, prostatitis, or interstitial cystitis  
• Biopsy-confirmed prostate, bladder, or urethral cancer  
• The following patients must undergo prostate biopsy with a minimum of 12 cores and have a negative histopathology report to be enrolled in the study:  
  ◦ digital rectal examination findings suspicious for prostate cancer  
  ◦ baseline PSA levels > 10 ng/mL  
  ◦ baseline PSA levels > 2.5 ng/mL and < 10 ng/mL and free PSA < 25% of total PSA |
- Cystoscopy findings suspicious for bladder cancer must undergo biopsy
  - Unable to have computer tomography angiography of the prostate imaging
  - Bladder atonia, neurogenic bladder disorder, or other neurological disorder that is impacting bladder function (e.g., multiple sclerosis, Parkinson’s disease, spinal cord injuries, etc.)
  - Urethral stricture, bladder neck contracture, sphincter abnormalities, bladder diverticulum, urinary obstruction due to causes other than BPH, or other potentially confounding bladder or urethral disease or condition
  - Acontractile detrusor.
  - Known upper tract renal disease
  - Cystolithiasis
  - Any known condition that limits catheter-based intervention or is a contraindication to embolization, such as intolerance to a vessel occlusion procedure or severe atherosclerosis. Known major iliac arterial occlusive disease
    - American Society of Anesthesiologists classification > 3 or severe medical debilitating condition
    - Baseline serum creatinine level > 1.8 mg/dL
    - Previous rectal surgery other than haemorrhoidectomy, or history of rectal disease
    - History of pelvic irradiation or radical pelvic surgery
    - Allergy to iodinated contrast agents

PUL
- Active urinary tract infections, prostatitis, or interstitial cystitis
- Biopsy-confirmed prostate, bladder, or urethral cancer
- The following men must undergo prostate biopsy with a minimum of 12 cores and have a negative histopathology report to be enrolled in the study:
  - Digital rectal examination findings suspicious for prostate cancer
  - Baseline PSA levels > 10 ng/mL
  - Baseline PSA levels > 2.5 ng/mL and < 10 ng/mL and free PSA < 25% of total PSA
  - Cystoscopy findings suspicious for bladder cancer must undergo biopsy
  - Significant median lobe enlargement
  - Large prostates, volume > 80 g
  - Bladder atonia, neurogenic bladder disorder, or other neurological disorder that is impacting bladder function (e.g., multiple sclerosis, Parkinson’s disease, spinal cord injuries, etc.)
  - Urethral stricture, bladder neck contracture, sphincter abnormalities, bladder diverticulum, urinary obstruction due to causes other than BPH, or other potentially confounding bladder or urethral disease or condition
  - Urethral conditions that may prevent insertion of a rigid 20-F cystoscope
  - Current urinary retention
  - Acontractile detrusor
  - Current gross haematuria
  - Known upper tract renal disease
  - Cystolithiasis
  - American Society of Anesthesiologists classification > 3 or severe medical debilitating condition
  - History of pelvic irradiation or radical pelvic surgery
  - Known allergy to nickel

**Total number of participants analyzed:** 37

**Group A (PAE)**
- Number of all participants analyzed: 21
  - Age: not reported
  - Prostate volume: not reported
  - PSA: not reported
  - IPSS (mean ± SD): 25.2 ± 7.0
  - $Q_{\text{max}}$: not reported
Pereira 2018  *(Continued)*

| Group B (PUL)        | Number of all participants analyzed: 16  
|                     | Age: not reported  
|                     | Prostate volume: not reported  
|                     | PSA: not reported  
|                     | IPSS (mean ± SD): 21.7 ± 8.95  
|                     | Q$_{\text{max}}$: not reported  

**Interventions**

- **Group A**: PAE  
- **Group B**: PUL  
- **Follow-up**: 6 months

| Outcomes          | IPSS/QoL  
|                  | How measured: IPSS questionnaire  
|                  | Time points measured: at the baseline; 3, 6, and 12 months  
|                  | Time points reported: at the baseline; 3 and 6 months (preliminary data)  
| Safety outcomes  | not reported  
| Subgroup         | none

| Notes            | Abstract only; the study is not completed.  
| Protocol         | NCT03043222  
| Language of publication | English

BPH: benign prostatic hyperplasia; IPSS: International Prostate Symptom Score; PSA: prostate-specific antigen; PAE: prostatic arterial embolization; PUL: prostatic urethral lift; Q$_{\text{max}}$: maximum flow rate; QoL: quality of life.

n: number of participants; NR: not reported; PUL: prostatic urethral lift; TURP: transurethral resection of prostate.

a: The number of participants analyzed for urological symptom scores.
b: The number of participants with adverse events.

CONTRIBUTIONS OF AUTHORS

JHJ: conception and study design, drafting the protocol, searching for trials, study selection, extracting data, assessing risk of bias, performing data analysis, interpretation of data, and drafting the review.

BR: drafting the protocol, searching for trials, study selection, extracting data, assessing risk of bias, performing data analysis, and drafting the review.

KAM: drafting the protocol, searching for trials, study selection, and drafting the review.

MB: drafting the protocol, and providing clinical and methodological advices on the review.

VN: drafting the protocol, and providing clinical and methodological advices on the review.

MHK: creating search strategies and searching for trials.

PD: conception and study design, providing clinical and methodological advice on the review, and final approval.

DECLARATIONS OF INTEREST

JHJ: none.

BR: none.

KAM: none.

MB: Boston Scientific (consultant for endourology and stone management), Auris Health (consultant for robotic surgery and endourology).

VN: none.

MHK: none.

PD: none.

DIFFERENCES BETWEEN PROTOCOL AND REVIEW

This review was based on a published protocol with differences as described here (Jung 2017).

• While we planned to include non-RCTs (see 'Types of studies'), no studies were found. Therefore, the planned methods for non-RCTs were not implemented in the review due to lack of data.

• Types of outcome measures: we used a minimal clinically important difference of 0.5 to assess quality of life based on a newly cited reference (Rees 2015). We analyzed retreatment outcomes for short term (12 months or less) and long term (greater than 12 months) separately.

• Types of outcome measures: we used proportion of participants with an indwelling catheter at postoperative 24 hours as a secondary outcome due to lack of data.

• Electronic searches: we additionally have searched Google scholar.

NOTES

We based parts of the Methods section of this review on a standard template developed by Cochrane Metabolic and Endocrine Disorders Group, which was modified and adapted for use by Cochrane Urology.
