ABSTRACT

Aim To evaluate the effect of regional implementation of a preconception counselling resource into routine diabetes care on pregnancy planning indicators.

Methods A preconception counselling DVD was distributed to women by diabetes care teams and general practices. Subsequently, in a prospective population-based study, pregnancy planning indicators were evaluated. The post-DVD cohort (n=135), including a viewed-DVD subgroup (n=58), were compared with an historical cohort (pre-DVD, n=114). Primary outcome was HbA1c at first diabetes-antenatal visit. Secondary outcomes included preconception folic acid consumption, planned pregnancy and HbA1c recorded in the 6 months preconception.

Results Mean first visit HbA1c was lower post-DVD vs. pre-DVD: 7.5% vs. 7.8% [58.4 vs. 61.8mmol/mol]; $p=0.12$), although not statistically significant. 53% and 20% of women with type 1 and 2 diabetes, respectively, viewed the DVD. The viewed-DVD subgroup were significantly more likely to have lower first visit HbA1c: 6.9% vs. 7.8% [52.1 vs. 61.8mmol/mol], $p<0.001$; planned pregnancy (88% vs. 59%, $P<0.001$); taken folic acid preconception (81% vs. 43%, $P=0.001$); and had HbA1c recorded preconception (88% vs. 53%, $P<0.001$) than the pre-DVD cohort.

Conclusions Implementation of a preconception counselling resource was associated with improved pregnancy planning indicators. Women with type 2 diabetes are difficult to reach. Greater awareness within primary care of the importance of preconception counselling among this population is needed.

Highlights

- Pregnancy planning and pre-pregnancy care uptake is poor among women with diabetes
- Poor preconception counselling is linked to poor pre-pregnancy care uptake
- Implementation of a preconception counselling resource improved pregnancy planning
- Women who engaged with the resource were better prepared for pregnancy
- Women with type 2 diabetes, typically cared for in primary care, are hard to reach

INTRODUCTION

Women with diabetes preceding pregnancy are at significant risk of adverse pregnancy outcomes when compared to the general maternity population, with higher rates of miscarriage, congenital malformations and stillbirth [1-7]. Planning pregnancy with the emphasis on optimizing glycemic control before conception reduces the risk of adverse outcomes [6-10]. All women with diabetes of childbearing potential should be counselled as to the risks associated with pregnancy and diabetes and of the benefits of planning for pregnancy. This 'conversation' with women, referred to as preconception counselling, should be incorporated regularly into routine diabetes outpatient visits and primary care consultations from adolescence according to national guidelines [11,12]. However, preconception counselling rates among women with diabetes remain low [13,14], with preconception counselling or contraception discussed with only 25% of women attending for annual review in one study [14].

In distinction from preconception counselling, pre-pregnancy care (PPC) is targeted specifically at women who are preparing for pregnancy [15]. While the emphasis of PPC is on glycemic control, other key components include prescription of high dose folic acid preconception and review of medications to ensure women avoid potentially teratogenic drugs. Despite the known benefits of PPC in reducing adverse outcomes, attendance remains suboptimal [8,16]; in one recent study only 27% of pregnant women attended formal PPC services [8]. While many women with diabetes are aware of the need to plan for pregnancy, they are often not aware of the reasons why [17,18]. To avoid unnecessary anxiety, women need to need to know why planning is important and must feel confident that they can effectively plan their pregnancies [18]. There is

a clear need to deliver accessible and appropriate information in relation to pregnancy planning.

To address low preconception counselling rates among women with diabetes and the consequences associated with lack of pregnancy planning knowledge, the Women with Diabetes Project team developed an educational preconception counselling DVD [17,19], which was evaluated among 97 women with diabetes for effectiveness in changing knowledge and attitudes towards preconception care. The study. Findings demonstrated effectiveness in increasing knowledge and enhancing attitudes of women with diabetes to preconception care [20], suggested that the DVD was an appropriate educational tool for use as a pre-pregnancy counselling resource to prepare women with diabetes for pregnancy. Since 2010, the DVD has been adopted throughout Northern Ireland as a preconception counselling resource. The aim of the current study was to evaluate the effect of implementation of the resource into routine care on indicators of pregnancy planning in women with diabetes. Furthermore, given that the prior evaluation showed that the resource significantly improved attitudes of women toward PPC, we hypothesised that women who both received and viewed the DVD would be more likely to plan for pregnancy resulting in significantly improved pregnancy planning indicators compared with women who conceived prior to implementation of the pre-pregnancy counselling resource.

METHODS

This study is a prospective nationwide population based study across all five regional diabetes-antenatal clinics in Northern Ireland comparing pregnancy planning indicators in pre- and post-preconception counselling resource cohorts. Study participants were women with pre-gestational diabetes who delivered/were expected to deliver between February 2012 and January 2013 (post-DVD cohort), including a viewed-DVD subgroup, compared with an historical cohort from the same five clinics (pre-DVD comparison cohort from between 1st September 2009 and 31st August 2010) (Figure 1). The intervention was a preconception counselling DVD distributed by diabetes care teams and general practices to women with diabetes of child bearing potential. This study was designed as a service evaluation utilising historic audit data as a comparison cohort and therefore did not require approval from a Research Ethics Committee. Local approvals were obtained.

Intervention development and implementation

A preconception counselling DVD resource was systematically developed using a combined user and multi-professional advisory group approach as described previously [19]. In brief, the content and style of the resource were guided by qualitative focus groups with women and by a multi-professional advisory group. The resource was underpinned by the Expanded Health Belief Model [21], is of 45-minutes duration and focuses on the importance of planning for pregnancy and on essential pregnancy planning advice in the form of a pre-pregnancy checklist. The DVD resource is women centred, featuring eight women with diabetes sharing their views and experiences, alongside an evidence-based commentary. The DVD has 3 parts: Part 1, “things you need to know”, encompassing sections entitled ‘contraception’,

'risks, 'why plan' and a 'pre-pregnancy checklist'; Part 2 "things you might not know" encompassing sections entitled 'support team', 'blood glucose targets, hypos and ketoacidosis' and 'diet'; and Part 3 "Things you may want to know!!" encompassing sections entitled '1st 2nd and 3rd trimester', 'Delivery' and 'Post-birth'.

Between October and December 2010, 6029 DVDs were distributed via healthcare professionals to all women with diabetes of childbearing age and potential within their care (Figure 1). All diabetes care teams within the five health and social care trusts in Northern Ireland (NI) adopted the resource as a preconception counselling resource. In addition, all general practices in NI were invited to request DVDs for distribution to patients under their care to ensure that women with type 2 diabetes, who did not attend secondary care, also received the resource. In total 34% of general practices actively engaged with the distribution process, with the remaining practices sent a DVD for information and for use within their practice. Awareness of the DVD among women with diabetes was further enhanced by promotion of the resource at local meetings, a local press release and a Diabetes UK mail out which coincided with the DVD launch. Diabetes care teams and general practices distributed the DVDs as appropriate to the needs of their patients, with some mailing DVDs to all women of child-bearing potential and others choosing to give DVDs face to face in clinic. Prior to the implementation of the DVD resource into routine care, no other educational resources in relation to preconception counselling/care for women with diabetes were widely available in NI.

A period of at least 5 months was allowed to elapse between distribution of the DVD resource and anticipated first conception for inclusion in the service evaluation. This time period allowed women who received the DVD from their healthcare professional the opportunity to view the resource and to take the necessary steps to

plan their pregnancies, including taking action to plan pregnancy (make lifestyle changes, attend PPC, commence folic acid and optimise blood glucose control).

Study Population

All women with diabetes preceding pregnancy (type 1 or type 2) who became pregnant after this period (first day of last menstrual period on or after 1st June 2011) and who attended one of the five joint diabetes-antenatal clinics in NI were eligible for inclusion. Data collection continued for 12 months.

Pregnancy planning indicators and maternal and neonatal outcomes were abstracted from patient notes by a midwife using a service evaluation tool, which replicated the audit tool used for the historical cohort. In addition the midwife inquired if the woman had received and viewed the DVD prior to conception, and the action they had taken as a consequence of watching the DVD.

Baseline comparison data were available from a regional audit of the same five regional joint diabetes-antenatal clinics across NI, involving all deliveries/expected deliveries in women with pre-gestational diabetes between 1st September 2009 and 31st August 2010 (pre-implementation of the DVD; pre-DVD comparison cohort).

The primary outcome was HbA1c at first joint diabetes-antenatal clinic visit in women post implementation of the DVD (post-DVD cohort) compared with the pre-DVD cohort in an intention to treat analysis. Secondary outcomes comprised other indicators of pregnancy planning including: pre-pregnancy folic acid use, gestational age at first antenatal visit, record of HbA1c measured in 6 months prior to pregnancy and documented use of contraception prior to pregnancy. In addition pregnancy planning

indicators were compared between women who both received and viewed the DVD (viewed-DVD) and those prior to the DVD launch (pre-DVD cohort). Maternal and neonatal outcomes included early pregnancy loss, congenital malformations and stillbirths. As women with type 1 and type 2 diabetes are at similar risk of poor pregnancy outcomes, and given the small numbers of women with type 2 diabetes in our population, analysis was carried out on all women with diabetes, type 1 and type 2 combined. Deprivation scores were obtained from the postcode of residence using the NI Multiple Deprivation Measure based on geographical area of residence to reflect socio-economic status [22]. Social deprivation scores were then divided into quintiles with women in the bottom quintile considered to be most socially deprived.

Statistical analysis

A sample size of 200 (100 in each of the pre- and post-DVD cohorts) was required to give an excess of 95% power to detect a 0.5% (or 5.5 mmol/mol) difference in mean HbA1c between cohorts as statistically significant ($P < 0.05$; two-tailed), assuming an inter-patient SD in HbA1c of 0.95% (or 10.4 mmol/mol) as observed in a similar population [23]. Assuming that 45% of the comparison cohort took folic acid pre-conception [23], the study size had in excess of 80% power to detect a difference of 20% (e.g. an increase from 45% to 65% taking folic acid pre-conception) as statistically significant ($P < 0.05$; two-tailed).

Comparisons between the comparison cohort (pre-DVD) and study cohort (post-DVD or viewed-DVD) were carried out using Chi-square or Fisher exact tests for categorical variables and two-tailed Student's *t* test for continuous variables. Logistic regression

(categorical variables) and multiple regression (continuous variables) were used to adjust these comparisons for diabetes type, diabetes duration, parity, social deprivation, age and booking hospital. Results were considered statistically significant at the 5% level.

RESULTS

Maternal Characteristics

In total, 135 women were included in the post DVD evaluation (post-DVD cohort), and 114 women from the baseline regional audit served as the comparison cohort (pre-DVD cohort). Characteristics of the women before and after the DVD launch are shown in Table 1. Women pre and post DVD launch were similar in age, ethnicity, social deprivation, BMI, diabetes duration and 1st joint antenatal-metabolic clinic visit clinical measures, but there were significantly fewer nulliparous women in the post-DVD cohort.

Pregnancy planning indicators

Pregnancy planning indicators of women before and after DVD distribution, and of the subgroup of women who both received and viewed the DVD prior to their pregnancy are shown in Table 2. There was a non-significant reduction in mean HbA1c at the 1st joint antenatal-metabolic clinic post-DVD compared to pre-DVD. Post-DVD, women were significantly more likely to have had HbA1c recorded in the 6 months preconception and there were also indications of improved pregnancy planning; women were more likely to have reported that the pregnancy was planned and to have taken folic acid preconception. Post-DVD, women were less likely to have a record in

their antenatal notes that they attended for or received pre-pregnancy counselling, however this was no longer significant when adjusted for confounding variables.

Effectiveness of distribution programme

While 62% of women reported receiving the DVD, 43% reported viewing the DVD prior to conception (viewed-DVD subgroup), with a larger proportion of women with type 1 diabetes receiving and viewing the DVD as outlined in figure 1.

Comparison of viewed-DVD subgroup to pre-implementation data

Characteristics of the viewed-DVD subgroup are shown in Table 1. Of those women who viewed the DVD, 22% were already attending for PPC, 36% proceeded to contact either their Diabetes Care Team or GP for PPC while 33% made lifestyle changes based on the advice given in the DVD but did not seek professional advice. Only 9% did not make changes or seek advice before pregnancy. The viewed-DVD subgroup had significantly lower HbA1c at the 1st antenatal-metabolic visit compared with the baseline comparator pre-DVD cohort as shown in Table 2. Compared with the pre-DVD cohort, the viewed-DVD subgroup were also significantly more likely to have planned their pregnancy ($P=0.001$), to have taken folic acid preconception ($P<0.001$), to have an HbA1c recorded in the 6 months prior to pregnancy ($P<0.001$), to have an HbA1c below 7.0% or 53mmol/mol ($P<0.05$) at the first visit and to be a current non-smoker ($P<0.05$). A similar proportion of women who viewed the DVD had a record of receiving pre-pregnancy counselling in their antenatal records as in the pre-DVD period.

Pregnancy progress and outcomes

Pregnancy progress and outcome indicators, before and after the DVD launch, including the subgroup of women who viewed the DVD prior to pregnancy are outlined in Table 3. Significant differences in glycemic control between the pre- and post-DVD cohorts were only evident in the 3rd trimester, most likely as a reflection of improved diabetes care during pregnancy. However, improved glycemic control in the 1st trimester was evident in the viewed-DVD subgroup compared with the pre-DVD cohort which may indicate improvement in pregnancy planning among those women who viewed the DVD.

Post-DVD significantly fewer women experienced fetal loss (miscarriage, termination of pregnancy or late fetal loss) compared to the pre-DVD cohort (14% vs. 4.4%), with the miscarriage/late fetal loss rate further reduced to 1.7% in the viewed-DVD subgroup. There were no stillbirths in the post-DVD cohort, compared with 3 (2.6%) in the pre-DVD cohort. There was one neonatal death in the post-DVD cohort. There was no significant difference between any of the cohorts for any other indicators of pregnancy progress or for any other maternal or neonatal outcomes.

DISCUSSION

The current study evaluates the implementation of an innovative DVD preconception counselling resource for women with diabetes into routine healthcare in NI. While

mean HbA1c at the first antenatal-metabolic visit was lower in the post-DVD cohort compared with the pre-DVD cohort, this did not reach statistical significance. However, women in the post-DVD cohort were significantly less likely to experience fetal loss which included miscarriage, termination of pregnancy and late fetal loss. For those women who viewed the DVD prior to conception, there was some evidence of enhanced pregnancy planning as indicated by improved glycemic control and folic acid uptake. Furthermore, the vast majority of women indicated that they made positive pregnancy planning decisions after viewing the resource, either by contacting a healthcare professional for PPC or actively making positive lifestyle changes.

While the impact of the resource on adverse pregnancy outcomes in this study is limited, demonstration of an effect was made difficult by the limited numbers of women and pragmatic nature of the study. In addition, our overall findings are in keeping with those of Willhoite and colleagues [24] who developed a programme to highlight the importance of preconception counselling to healthcare providers and women with diabetes in Maine, USA, in a region where only 34% of 185 pregnancies occurred in women who had received counselling. In addition, Pearson and colleagues [7] have previously reported on the benefits of planning pregnancy and formal pre-pregnancy care in relation to a similar composite adverse pregnancy outcome in women with type 1 diabetes. Tripahti and colleagues [25] also found improved first trimester glycemic control in women receiving preconception counselling. In the present study, HbA1c was non-significantly lower in the post-DVD cohort, however, this reduction reached significance in those who viewed the DVD. The positive impact of the implementation of the DVD into routine care on foetal loss is likely be a reflection of the comprehensive

nature of pregnancy planning, and the fact that planning advice goes beyond glycemic control to include advice on folic acid supplementation, medications and lifestyle.

Prior to the DVD launch, we successfully evaluated the DVD among women with diabetes and reported the effectiveness of the DVD in increasing knowledge and enhancing attitudes of women with diabetes to PPC [20]. While similar findings of effectiveness have been reported for a preconception counselling resource aimed at adolescents in the US [26], the longer term impact on pregnancy planning in that cohort remains unknown as no pregnancies have yet been reported.

A particular strength of this study is the evaluation of the resource over a longer period using a population based approach, where the impact on pregnancy planning indicators in a subsequent pregnancy is explored. This study encompasses a large geographic region and captured maternal and neonatal outcomes for all women with diabetes delivering in the region, allowing an extensive evaluation of distribution and uptake of this resource.

However, our study has a number of limitations. It was not possible to determine which women also benefited from structured PPC, and antenatal records of pre-pregnancy counselling are likely to be a mixture of preconception counselling and structured PPC. In addition, the majority of women in this study were of white ethnicity, reflecting the background population of Northern Ireland, making the findings of this study generalizable to white populations. While data collection methodology was carefully repeated from pre to post audit it is well known that capture of early miscarriage in secondary care is difficult as some women may have miscarried before attendance at

the first diabetes-antenatal clinic. Finally, we acknowledge that a randomised controlled trial would have been the ideal study design to fully determine effectiveness of the DVD. However, as initial feasibility work determined that it was not feasible to carry out a regional RCT within the primary care setting, and thus to reach as many women with diabetes as possible throughout the region, irrespective of pregnancy plans, the current study design was chosen. The authors acknowledge that a major limitation of the design is that the observed changes may have occurred for other reasons than having seen the DVD. Nonetheless, the findings of this evaluation indicate that implementation of the DVD had a positive impact on outcomes, and that viewing the DVD is associated with improved pregnancy planning indicators, regardless of process.

Despite a targeted distribution campaign, our study shows that reaching all women with diabetes, particularly those with type 2 diabetes, remains a challenge. This is in keeping with other studies where pre-pregnancy care rates were lower in women with type 2 diabetes [16,25,27]. In our study only 34% of GP practices actively engaged with the distribution programme, in contrast to all diabetes care teams. As GPs are often the sole providers of diabetes care in type 2 diabetes, our study highlights the urgent need for primary care to further engage in preconception counselling for women with diabetes, especially those with type 2 diabetes. A recent study reported that GPs and secondary care professionals differ in their perception of the number of women with diabetes requiring preconception care and regarding the role of GPs in that care [28]. A greater awareness of the importance of preconception counselling is needed and all healthcare professionals must avail of every opportunity to have that 'conversation' with women. A resource such as this DVD is an ideal tool to assist

healthcare professionals in offering preconception counselling to women with diabetes. In this resource roll-out, 30% of those women who said they received the DVD did not watch it. To maximise impact and reach, and address non-engagement with the resource the Women with Diabetes project team have subsequently converted the DVD to a mobile friendly website (www.womenwithdiabtes.net) [29], which now includes an e-learning continuing professional development resource for healthcare professionals. Finally, women who viewed the DVD were also less likely to come from a deprived background, again in keeping with other studies [16,25], and further highlighting the continuing need to develop novel approaches to reach socially deprived communities.

This regional evaluation of the implementation of a preconception counselling resource for women with diabetes into routine care demonstrates improved pregnancy planning indicators post implementation.. While challenges remain to engage women, those who viewed the resource were better prepared for pregnancy in terms of glycemic control and folic acid uptake. Our findings also highlight the ongoing challenges of reaching all women with diabetes, in particular those with type 2 diabetes and those from socially deprived backgrounds. Future programmes need to consider a joint approach between primary and secondary care services to increase reach of educational resources and hence maximize benefit for all women with diabetes.

Table 1. Characteristics of pregnant women with diabetes in Northern Ireland before and after the DVD launch, and of the subgroup of women who viewed the DVD prior to their pregnancy

	Pre DVD (N = 114)	Post DVD (N = 135)	P value*	Viewed DVD (N = 58)	P value**
Age, yr, mean (SD) [n]	30.9 (6.5) [114]	31.3 (5.6) [135]	0.60	32.0 (4.7) [58]	0.23
White ethnicity, n/N (%)	111/114 (97.4)	129/135 (95.6)	0.51	56/58 (96.6)	1.00
Type of Diabetes, n/N (%)					
Type 1	88 (77.2)	95 (70.4)	0.22	50 (86.2)	0.16
Type 2	26 (22.8)	40 (29.6)		8 (13.8)	
Deprivation category, n/N (%)					
1 (most deprived)	31/114 (27.2)	28/134 (20.9)	0.02 †	7/57 (12.3)	0.001 †
2	27/114 (23.7)	23/134 (17.2)		9/57 (15.8)	
3	28/114 (24.6)	31/134 (23.1)		15/57 (26.3)	
4	17/114 (14.9)	29/134 (21.6)		12/57 (21.1)	
5 (least deprived)	11/114 (9.6)	23/134 (17.2)		14/57 (24.6)	
Nulliparous, n/N (%)	52/114 (45.6)	44/135 (32.6)	0.035	23/58 (39.7)	0.46
Diabetes duration, yr, mean (SD) [n]	12.0 (8.5) [113]	12.1 (8.7) [135]	0.94	15.6 (8.8) [58]	0.01
BMI at booking, kg/m², mean (SD) [n]	28.2 (5.7) [102]	28.8 (6.9) [133]	0.44	26.7 (5.0) [58]	0.11
Overweight /Obese (BMI \geq25kg/m²) at booking, n/N (%)	65/102 (63.7)	86/133 (64.7)	0.88	31/58 (53.4)	0.20

Data are mean (standard deviation) or n/N (%) unless otherwise stated. *Pre DVD vs. Post DVD; ** Pre DVD vs. Watched DVD; Comparisons made using the Student's *t*-test for continuous variables and the chi-squared test for categorical variables. †Chi-squared test for trend.

Table 2. Pregnancy planning indicators of women with diabetes in Northern Ireland before and after the DVD launch, and of the subgroup of women who viewed the DVD prior to their pregnancy

	Pre DVD (N = 114)	Post DVD (N = 135)	Mean difference or Odds ratio (95%CI) unadjusted* adjusted†	P value	Viewed DVD (N = 58)	Mean difference or Odds ratio (95%CI) unadjusted** adjusted†	P value
