# NON-COMMUTATIVE LOCALISATION AND FINITE DOMINATION OVER STRONGLY $\mathbb{Z}$ -GRADED RINGS

THOMAS HÜTTEMANN

ABSTRACT. Let  $R = \bigoplus_{k=-\infty}^{\infty} R_k$  be a strongly  $\mathbb{Z}$ -graded ring, and let  $C^+$  be a chain complex of modules over the positive subring  $P = \bigoplus_{k=0}^{\infty} R_k$ . The complex  $C^+ \otimes_P R_0$  is contractible (*resp.*,  $C^+$  is  $R_0$ -finitely dominated) if and only if  $C^+ \otimes_P L$  is contractible, where  $L$  is a suitable non-commutative localisation of  $P$ . We exhibit universal properties of these localisations, and show by example that an  $R_0$ -finitely dominated complex need not be  $P$ -homotopy finite.

## Introduction

**Finite domination.** Let  $R_0$  be a unital ring, possibly non-commutative. A chain complex  $C$  of  $R_0$ -modules is called  *$R_0$ -finitely dominated* if it is a retract up to homotopy of a bounded complex of finitely generated free  $R_0$ -modules. When  $C$  is bounded and consists of projective  $R_0$ -modules,  $C$  is  $R_0$ -finitely dominated if and only if  $C$  is homotopy equivalent to a bounded complex of finitely generated projective  $R_0$ -modules [Ran85, Proposition 3.2 (ii)]; this is sometimes expressed by saying that  $C$  is “of type FP”.

**Non-commutative localisation.** A  $K$ -ring is a unit-preserving homomorphism  $K \longrightarrow S$  of unital rings with domain  $K$ . Let  $\Sigma$  be a set of homomorphisms of finitely generated projective (right)  $K$ -modules. The  $K$ -ring  $f : K \longrightarrow S$  is called  *$\Sigma$ -inverting* if all the induced maps

$$\sigma \otimes S : P \otimes_K S \longrightarrow Q \otimes_K S, \quad (\sigma : P \longrightarrow Q) \in \Sigma$$

are isomorphisms of  $S$ -modules. The *non-commutative localisation of  $K$  with respect to  $\Sigma$*  is the  $K$ -ring  $\lambda_\Sigma : K \longrightarrow \Sigma^{-1}K$  which is initial in the category of  $\Sigma$ -inverting  $K$ -rings; it exists for all  $\Sigma$  [Sch85, Theorem 4.1].

**Detecting contractibility and finite domination using non-commutative localisation.** Let  $C^+$  be a bounded chain complex consisting of finitely generated free modules over the polynomial ring  $R_0[t]$ , where  $t$  is a (central) indeterminate commuting with all elements of  $R_0$ . Our starting point is the following pair of results obtained by RANICKI:

**Theorem.** *There are sets  $\tilde{\Omega}_+$  and  $\Omega_+$  of square matrices with entries in  $R_0[t]$ , considered as maps between finitely generated free  $R_0[t]$ -modules, such that*

- (A) *The induced complex  $C^+ \otimes_{R_0[t]} R_0$  is contractible (tensor product via the map  $R_0[t] \longrightarrow R_0, t \mapsto 0$ ) if and only if the induced chain complex  $C^+ \otimes_{R_0[t]} \tilde{\Omega}_+^{-1} R_0[t]$  is contractible [Ran98, Proposition 10.13];*
- (B)  *$C^+$  is  $R_0$ -finitely dominated if and only if the induced chain complex  $C^+ \otimes_{R_0[t]} \Omega_+^{-1} R_0[t]$  is contractible [Ran98, Proposition 10.11].*

**Content of the paper.** RANICKI's results are extended to a larger class of rings containing polynomial rings as special examples. Let  $R = \bigoplus_{k \in \mathbb{Z}} R_k$  be a  $\mathbb{Z}$ -graded ring. The polynomial ring  $R[t]$  has a subring, denoted  $R_*[t]$ , consisting of those polynomials  $\sum_k r_k t^k$  with  $r_k \in R_k$ ; up to the ring isomorphism symbolised by  $t \mapsto 1$ , this is the  $\mathbb{N}$ -graded ring  $\bigoplus_{k \geq 0} R_k$ . We will show that *the results above remain valid mutatis mutandis if the polynomial ring  $R_0[t]$  is replaced by the  $\mathbb{N}$ -graded ring  $R_*[t]$  throughout, where in (B) we additionally demand the  $\mathbb{Z}$ -graded ring  $R$  to be strongly graded.* This last conditions means that the multiplication map  $R_k \otimes_{R_0} R_{-k} \longrightarrow R_0$  is surjective for all  $k \in \mathbb{Z}$ . It is surprising that the results rest exclusively on the (strongly) graded structure of the underlying rings, and not on the specific form of polynomial rings in one indeterminate.

**Motivation.** Finiteness conditions for chain complexes are studied in algebraic topology [Ran85, Ran98] and other subjects (e.g.,  $\Sigma$ -invariants in geometric group theory). The present paper develops aspects of the theory from a purely algebraic point of view, shifting the focus from (LAURENT) polynomial rings to the larger class of (strongly)  $\mathbb{Z}$ -graded rings instead.

Strong gradings were introduced by DADE [Dad80] to capture the quintessential properties of group rings. The extent to which strongly  $\mathbb{Z}$ -graded rings behave like LAURENT polynomial rings is in fact astonishing; examples include the splitting of the algebraic  $K$ -theory of the projective line (HÜTTEMANN and MONTGOMERY [HM20]), the relation between finite domination and NOVIKOV homology (HÜTTEMANN and STEERS [HS17]), and the fundamental theorem in algebraic  $K$ -theory for strongly  $\mathbb{Z}$ -graded rings (HÜTTEMANN [Hüt20]). The present paper adds further entries to the list of results that transfer to the strongly graded setting. Lest the reader gains the impression that this is a straightforward transcription we remark that, unlike the *statements* of the results, the *proofs* do not carry over mechanically. We also highlight in §7 a subtle example of a finiteness property that does *not* carry over as expected.

**Organisation of the paper.** The paper is divided into three parts, discussing  $\mathbb{Z}$ -graded rings and non-commutative localisation, contractible complexes, and finite domination respectively. Independently, the material is divided into numbered sections.

**Conventions.** All rings are unital, ring homomorphisms preserve unity, and modules are unital and right, unless stated otherwise.

## Part 1. Algebraic background

### 1. CONSTRUCTING NEW RINGS FROM A $\mathbb{Z}$ -GRADED RING

For a (unital) ring  $R$  we can construct various polynomial and power series rings using a central indeterminate  $t$ ; the rings  $R[t]$ ,  $R[t^{-1}]$ ,  $R[t, t^{-1}]$ ,  $R[[t]]$ ,  $R[[t^{-1}]]$ ,  $R((t)) = R[[t]][1/t]$  and  $R((t^{-1})) = R[[t^{-1}]][1/t^{-1}]$  will be of relevance. Elements of these rings can be written as formal sums  $\sum_k r_k t^k$ , with suitable restrictions on the number and sign of indices of non-zero coefficients  $r_k$ .

Suppose now that  $R = \bigoplus_{k \in \mathbb{Z}} R_k$  is equipped with the structure of a  $\mathbb{Z}$ -graded ring. We can then define subrings of the rings above by requiring that for all  $k \in \mathbb{Z}$  the coefficient  $r_k$  of  $t^k$  lies in  $R_k$ . The resulting rings will be denoted by the symbols  $R_*[t]$ ,  $R_*[t^{-1}]$ ,  $R_*[t, t^{-1}]$ ,  $R_*[[t]]$ ,  $R_*[[t^{-1}]]$ ,  $R_*((t))$  and  $R_*((t^{-1}))$ , respectively. For example,

$$R_*((t)) = \bigcup_{p \geq 0} \left\{ \sum_{k=-p}^{\infty} r_k t^k \mid \forall k: r_k \in R_k \right\}.$$

As a graded ring,  $R_*[t, t^{-1}] = R$  via the map symbolically described as  $t \mapsto 1$ . Similarly  $R_*[t] = \bigoplus_{k \geq 0} R_k$  and  $R_*[t^{-1}] = \bigoplus_{k \leq 0} R_k$ . We write

$$t^n R_*[t] = \bigoplus_{k \geq n} R_k \quad \text{and} \quad t^n R_*[t^{-1}] = \bigoplus_{k \leq n} R_k, \quad (1.1)$$

which are (left and right) modules over  $R_*[t]$  and  $R_*[t^{-1}]$ , respectively; the symbol  $t^n R_*[[t^{-1}]]$  denotes the  $R_*[[t^{-1}]]$ -module of formal power series involving powers of  $t$  not exceeding  $n$ .

For later use we introduce notation for truncation of formal power series. For  $-\infty \leq \ell < u \leq \infty$  we define

$$\text{tr}_\ell^u: \sum_{k \in \mathbb{Z}} r_k t^k \mapsto \sum_{k=\ell}^u r_k t^k,$$

and abbreviations in the special cases  $\ell = -\infty$  and  $u = \infty$ ,

$$\text{tr}^u = \text{tr}_{-\infty}^u \quad \text{and} \quad \text{tr}_\ell = \text{tr}_\ell^\infty. \quad (1.2)$$

For example, the map

$$\mathrm{tr}^0: R_*[t] \longrightarrow R_0, \quad \sum_{k=0}^d r_k t^k \mapsto r_0 \quad (1.3)$$

is the “constant-coefficient” ring homomorphism which is given symbolically by  $t \mapsto 0$ .

## 2. STRONGLY GRADED RINGS

**Strongly graded rings and partitions of unity.** Let  $R = R_*[t, t^{-1}]$  be a  $\mathbb{Z}$ -graded ring. A finite sum expression  $1 = \sum_j \alpha_j^{(n)} \beta_j^{(-n)}$  with  $\alpha_j^{(n)} \in R_n$  and  $\beta_j^{(-n)} \in R_{-n}$  is called a *partition of unity of type  $(n, -n)$* . The ring  $R_*[t, t^{-1}]$  is called *strongly graded* (DADE [Dad80, §1]) if there exists a partition of unity of type  $(n, -n)$  for every  $n \in \mathbb{Z}$ ; equivalently, if the multiplication map

$$\pi_n: R_n \otimes_{R_0} R_{-n} \longrightarrow R_0, \quad x \otimes y \mapsto xy \quad (2.1)$$

is surjective for every  $n \in \mathbb{Z}$ .

**Lemma 2.2.** *If  $\pi_n$  is onto, then  $\pi_n$  is an isomorphism of  $R_0$ - $R_0$ -bimodules.*

*Proof.* The map  $\pi_n$  is clearly left and right  $R_0$ -linear. If  $\pi_n$  is onto we can choose a partition of unity  $1 = \sum_j \alpha_j^{(n)} \beta_j^{(-n)}$  and define the right  $R_0$ -linear map

$$\kappa_n: R_0 \longrightarrow R_n \otimes_{R_0} R_{-n}, \quad x \mapsto \sum_j \alpha_j^{(n)} \otimes \beta_j^{(-n)} x.$$

Then we calculate

$$\kappa_n \pi_n(x \otimes y) = \sum_j \alpha_j^{(n)} \otimes \beta_j^{(-n)} xy = \sum_j \alpha_j^{(n)} \beta_j^{(-n)} x \otimes y = x \otimes y$$

(using  $\beta_j^{(-n)} x \in R_0$ ) so that  $\pi_n$  is injective.  $\square$

**Lemma 2.3.** *Let  $R = R_*[t, t^{-1}]$  be a  $\mathbb{Z}$ -graded ring, and let  $1 = \sum_i \alpha_i^{(m)} \beta_i^{(-m)}$  and  $1 = \sum_j \bar{\alpha}_j^{(n)} \bar{\beta}_j^{(-n)}$  be two partitions of unity of types  $(m, -m)$  and  $(n, -n)$ , respectively. Then*

$$1 = \sum_{i,j} (\alpha_i^{(m)} \alpha_j^{(n)}) \cdot (\beta_j^{(-n)} \beta_i^{(-m)})$$

*is a partition of unity of type  $(m+n, -m-n)$ .*  $\square$

**Corollary 2.4.** *Partitions of unity of types  $(1, -1)$  and  $(-1, 1)$  exist within the  $\mathbb{Z}$ -graded ring  $R_*[t, t^{-1}]$  if and only if it is strongly  $\mathbb{Z}$ -graded.*  $\square$

By direct calculation, similar to the proof of Lemma 2.2 above, one verifies:

**Lemma 2.5.** *Suppose that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring, and let  $m \in \mathbb{Z}$ . The multiplication map*

$$t^{-m}R_*[t] \otimes_{R_*[t]} R_*[t, t^{-1}] \longrightarrow R_*[t, t^{-1}], \quad x \otimes y \mapsto xy$$

is an isomorphism of  $R_*[t]$ - $R_*[t, t^{-1}]$ -bimodules, with inverse given by

$$z \mapsto \sum_j \alpha_j^{(-m)} \otimes \beta_j^{(m)} z$$

for a partition of unity  $1 = \sum_j \alpha_j^{(-m)} \beta_j^{(m)}$  of type  $(-m, m)$ .  $\square$

Note that the inverse is independent from the choice of partition of unity (since the multiplication map is). — For later use, we record an important categorical property of strongly  $\mathbb{Z}$ -graded rings:

**Lemma 2.6.** *Let  $R = R_*[t, t^{-1}]$  be a strongly  $\mathbb{Z}$ -graded ring. The inclusion  $\beta: R_*[t] \xrightarrow{\subset} R_*[t, t^{-1}]$  is an epimorphism in the category of (unital) rings.*

*Proof.* Let  $f, g: R_*[t, t^{-1}] \longrightarrow S$  be ring homomorphisms satisfying the equality  $f\beta = g\beta$ . We need to show  $f = g$ . For this, let  $x \in R_k$  be homogeneous of degree  $k \in \mathbb{Z}$ . If  $k \geq 0$  we have  $f(x) = f\beta(x) = g\beta(x) = g(x)$ . Otherwise, choose a partition of unity  $1 = \sum_j \alpha_j^{(k)} \beta_j^{(-k)}$  of type  $(k, -k)$ . Then  $\beta_j^{(-k)}$  and  $\beta_j^{(-k)}x$  lie in  $R_*[t]$ . Thus  $f(\beta_j^{(-k)}x) = g(\beta_j^{(-k)}x)$ , and we calculate

$$\begin{aligned} f(x) &= g(1) \cdot f(x) \\ &= \sum_j g(\alpha_j^{(k)} \beta_j^{(-k)}) \cdot f(x) = \sum_j g(\alpha_j^{(k)}) \cdot g(\beta_j^{(-k)}) \cdot f(x) \\ &= \sum_j g(\alpha_j^{(k)}) \cdot f(\beta_j^{(-k)}) \cdot f(x) = \sum_j g(\alpha_j^{(k)}) \cdot f(\beta_j^{(-k)}x) \\ &= \sum_j g(\alpha_j^{(k)}) \cdot g(\beta_j^{(-k)}x) = \sum_j g(\alpha_j^{(k)} \beta_j^{(-k)}x) = g(x). \end{aligned}$$

$\square$

**Finiteness properties of strongly graded rings.** The homogeneous components of strongly graded rings are finitely generated projective modules over the degree-0 subring.

**Lemma 2.7.** *Suppose that  $R = R_*[t, t^{-1}]$  is a  $\mathbb{Z}$ -graded ring that admits a partition of unity of type  $(1, -1)$ . Then for all  $n \geq 1$ ,*

- $R_n$  is finitely generated projective as a right  $R_0$ -module;
- $R_{-n}$  is finitely generated projective as a left  $R_0$ -module.

*Similarly, if  $R = R_*[t, t^{-1}]$  admits a partition of unity of type  $(1, -1)$ , then for all  $n \geq 1$ ,*

- $R_n$  is finitely generated projective as a left  $R_0$ -module;
- $R_{-n}$  is finitely generated projective as a right  $R_0$ -module.

*Proof.* Let  $n \geq 1$ , and let  $1 = \sum_j \alpha_j^{(n)} \beta_j^{(-n)}$  be a partition of unity of type  $(n, -n)$  (existence is guaranteed by Lemma 2.3). Define

$$f_j: R_n \longrightarrow R_0, \quad x \mapsto \beta_j^{(-n)} x.$$

The maps  $f_j$  are right  $R_0$ -linear, and for all  $x \in R_n$  we calculate

$$\sum_j \alpha_j^{(n)} \cdot f_j(x) = \sum_j \alpha_j^{(n)} \beta_j^{(-n)} x = x$$

so that  $(\alpha_j^{(n)}, f_j)$  is a dual basis for  $R_n$ . It follows that  $R_n$  is a finitely generated projective right  $R_0$ -module by the dual basis lemma. — All the remaining claims are proved in a similar manner.  $\square$

**Corollary 2.8.** *Suppose that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring.*

- (1) *For all  $n \in \mathbb{Z}$ , the homogeneous component  $R_n$  of  $R_*[t, t^{-1}]$  is a finitely generated projective left  $R_0$ -module and a finitely generated projective right  $R_0$ -module; in fact,  $R_n$  is an invertible  $R_0$ -bimodule.*
- (2) *If  $M$  is a projective (left or right)  $R_*[t, t^{-1}]$ -module, then  $M$  is a projective (left or right)  $R_0$ -module (with module structure given by restriction of scalars). Similarly, any projective left or right module over  $R_*[t]$  or  $R_*[t^{-1}]$  is a projective  $R_0$ -module.*
- (3) *There exists an isomorphism  $R_{-m} \otimes_{R_0} R_*[t] \cong t^{-m} R_*[t]$  of finitely generated projective right  $R_*[t]$ -modules, for every  $m \in \mathbb{Z}$ . Similarly, there exists an isomorphism  $R_m \otimes_{R_0} R_*[t^{-1}] \cong t^m R_*[t^{-1}]$  of finitely generated projective right  $R_*[t^{-1}]$ -modules.*
- (4) *For all  $m \in \mathbb{Z}$ , the module  $t^{-m} R_*[t]$  is an invertible  $R_*[t]$ -bimodule, and hence is finitely generated projective as a left and right  $R_*[t]$ -module. Similarly,  $t^m R_*[t^{-1}]$  is an invertible  $R_*[t^{-1}]$ -bimodule, and hence is finitely generated projective as a left and right  $R_*[t^{-1}]$ -module.*

*Proof.* Statements (1) and (2) follow from Lemma 2.2, Corollary 2.4 and Lemma 2.7. To prove (3) it is enough, in view of (1), to establish the

isomorphism. Let  $1 = \sum_j \alpha_j^{(-m)} \beta_j^{(m)}$  be a partition of unity of type  $(-m, m)$ . Then the multiplication map  $\pi: R_{-m} \otimes_{R_0} R_*[t] \xrightarrow{\cong} t^{-m} R_*[t]$ , sending  $x \otimes y$  to  $xy$ , has inverse given by  $\rho: z \mapsto \sum_j \alpha_j^{(-m)} \otimes \beta_j^{(m)} z$ . Indeed, by straightforward calculation,  $\pi\rho(z) = \sum_j \alpha_j^{(-m)} \beta_j^{(m)} z = z$  and

$$\rho\pi(x \otimes y) = \sum_j \alpha_j^{(-m)} \otimes \beta_j^{(m)} xy = \sum_j \alpha_j^{(-m)} \beta_j^{(m)} x \otimes y = x \otimes y$$

since  $\beta_j^{(m)} x \in R_0$ . — The proof of (4) is similar, using partitions of unity to show that  $t^m R_*[t]$  is the inverse  $R_*[t]$ -bimodule of  $t^{-m} R_*[t]$ .  $\square$

### 3. PROTO-NULL HOMOTOPIES AND PROTO-CONTRACTIONS

Let  $C$  and  $C'$  be chain complexes of right modules over the unital ring  $K$ , with differentials  $d = d_k: C_k \longrightarrow C_{k-1}$  and  $d' = d'_k$ . A *proto-contraction* of  $C$  consists of module homomorphisms  $s = s_k: C_k \longrightarrow C_{k+1}$  such that  $ds + sd: C_k \longrightarrow C_k$  is an automorphism of  $C_k$  for all  $k \in \mathbb{Z}$ . Somewhat more generally, a  $(C, C')$ -*proto-null homotopy* consists of module homomorphisms  $t = t_k: C_k \longrightarrow C'_{k+1}$  such that  $g_k = d't + td: C_k \longrightarrow C'_k$  is an isomorphism for all  $k \in \mathbb{Z}$ . In fact, the maps  $g_k$  define a chain isomorphism  $g: C \xrightarrow{\cong} C'$ , and the maps  $t_k$  define a null homotopy of  $g$ .

**Lemma 3.1.** *A chain complex  $C$  admits a proto-contraction if and only if it is contractible. The chain complexes  $C$  and  $C'$  admit a  $(C, C')$ -proto-null homotopy if and only if  $C \cong C'$  and  $C$  is contractible.*

*Proof.* A proto-contraction is, by definition, the same as a  $(C, C)$ -proto-null homotopy, so it suffices to prove the second statement. If there exists a chain isomorphism  $g: C \longrightarrow C'$  with  $C$  contractible, we can choose a null homotopy  $t$  of  $g$  which constitutes a  $(C, C')$ -proto-null homotopy. Conversely, any  $(C, C')$ -proto-null homotopy  $t$  determines a null homotopic chain isomorphism  $g = d't + td$ , as explain above. Then  $\text{id}_C = g^{-1}g$  is null homotopic as well so that  $C$  is contractible.  $\square$

Given a ring homomorphism  $f: K \longrightarrow S$ , the family of maps  $s_k$  is called an  $f$ -*proto-contraction* if the maps  $s_k \otimes \text{id}$  form a proto-contraction of the induced complex  $f_*(C) = C \otimes_K S$ . Similarly, the family of maps  $t_k$  is called a  $(C, C')$ - $f$ -*proto-null homotopy* if the maps  $t_k \otimes \text{id}$  form a  $(C \otimes_K S, C' \otimes_K S)$ -proto-null homotopy.

We are interested in proto-contractions for the following reason. Suppose we are given  $C$  and  $f$  as before, and another ring homomorphism

$g: S \longrightarrow T$ . If  $f_*(C) = C \otimes_K S$  is contractible then  $(gf)_*(C) = C \otimes_K T \cong C \otimes_K S \otimes_S T$  is contractible as well, since taking tensor product preserves homotopies. If, however,  $(gf)_*(C)$  is contractible it is not guaranteed that  $f_*(C)$  is contractible. In favourable circumstances, a contraction of  $(gf)_*(C)$  gives rise to a sequence of maps  $s_k: C_k \longrightarrow C_{k+1}$  which can be shown, thanks to special properties of the maps  $f$  and  $g$ , to be an  $f$ -proto-contraction.

#### 4. REMARKS ON NON-COMMUTATIVE LOCALISATION

Let  $K$  denote an arbitrary unital, possibly non-commutative ring. For the reader's convenience we collect some standard facts about non-commutative localisation

**Proposition 4.1.** *Let  $\Sigma$  be a set of homomorphisms of finitely generated projective  $K$ -modules, and let  $f: K \longrightarrow S$  be a  $K$ -ring. Write  $\lambda_\Sigma: K \longrightarrow \Sigma^{-1}K$  for the non-commutative localisation of  $K$  with respect to  $\Sigma$ .*

- (1) *If  $f$  is  $\Sigma$ -invertible and injective, then  $\lambda_\Sigma$  is injective.*
- (2) *The non-commutative localisation  $\lambda_\Sigma: K \longrightarrow \Sigma^{-1}K$  is an epimorphism in the category of unital rings.*
- (3) *Suppose that  $\Sigma$  is the set of all those square matrices  $M$  with entries in  $K$  such that  $f(M)$  is invertible over  $S$ ; we consider a square matrix of size  $k$  as a map of finitely generated free modules  $\mu: K^k \longrightarrow K^k$  so that  $f(M)$  represents the induced map  $\mu \otimes S: S^k \longrightarrow S^k$ . Let  $A$  be a square matrix with entries in  $K$ . Then  $A \in \Sigma$  if and only if  $\lambda_\Sigma(A)$  is invertible over the ring  $\Sigma^{-1}K$ .*

*Proof.* (1) As  $f$  is  $\Sigma$ -invertible, it factors as  $K \xrightarrow{\lambda_\Sigma} \Sigma^{-1}K \longrightarrow S$ . This forces  $\lambda_\Sigma$  to be injective if  $f$  is.

(2) Suppose we have two ring homomorphisms  $\alpha, \beta: \Sigma^{-1}K \longrightarrow T$  with  $\alpha\lambda_\Sigma = \beta\lambda_\Sigma$ . This common composition is certainly  $\Sigma$ -invertible, so factorises *uniquely* through  $\lambda_\Sigma$ . This means precisely that  $\alpha = \beta$ , as required.

(3) Since the map  $f$  is  $\Sigma$ -invertible, it factors as  $K \xrightarrow{\lambda_\Sigma} \Sigma^{-1}K \xrightarrow{\tilde{f}} S$ . If  $A$  is a square matrix in  $\Sigma$  then  $\lambda_\Sigma(A)$  is invertible in  $\Sigma^{-1}K$ , by definition of non-commutative localisation. If the square matrix  $A$  with entries in  $K$  is such that  $\lambda_\Sigma(A)$  is invertible, then  $\tilde{f}\lambda_\Sigma(A) = f(A)$  is invertible over  $S$  so that  $A \in \Sigma$  by the specific choice of  $\Sigma$ .  $\square$

We will have occasion to use the following construction of pushout squares:

**Proposition 4.2.** *Let  $\Sigma$  be a set of homomorphisms of finitely generated projective  $K$ -modules, and let  $f: K \longrightarrow S$  be a ring homomorphism. The*

square in Fig. 1 is a pushout in the category of unital rings, where  $f_*(\Sigma)$  de-

$$\begin{array}{ccc}
 K & \xrightarrow{\lambda_\Sigma} & \Sigma^{-1}K \\
 f \downarrow & \lrcorner & \downarrow \bar{f} \\
 S & \xrightarrow{\lambda_{f_*(\Sigma)}} & f_*(\Sigma)^{-1}S
 \end{array}$$

FIGURE 1. A pushout square in the category of unital rings

notes the set of induced maps  $\sigma \otimes S: P \otimes_K S \longrightarrow Q \otimes_K S$  with  $\sigma: P \longrightarrow Q$  an element of  $\Sigma$ . The ring homomorphism  $\bar{f}$  is obtained from the universal property of  $\lambda_\Sigma$  as the composition  $\lambda_{f_*(\Sigma)} \circ f$  is  $\Sigma$ -inverting. — In other words, given ring homomorphisms  $\beta: S \longrightarrow T$  and  $\alpha: \Sigma^{-1}K \longrightarrow T$  such that  $\alpha \circ \lambda_\Sigma = \beta \circ f$  there exists a uniquely determined ring homomorphism  $v: f_*(\Sigma)^{-1}S \longrightarrow T$  with  $\beta = v \circ \lambda_{f_*(\Sigma)}$  and  $\alpha = v \circ \bar{f}$ , cf. Fig. 2.

$$\begin{array}{ccc}
 K & \xrightarrow{\lambda_\Sigma} & \Sigma^{-1}K \\
 f \downarrow & & \downarrow \bar{f} \\
 S & \xrightarrow{\lambda_{f_*(\Sigma)}} & f_*(\Sigma)^{-1}S
 \end{array}
 \begin{array}{l}
 \nearrow \alpha \\
 \searrow \beta \\
 \text{---} \exists! v \text{---}
 \end{array}
 \longrightarrow T$$

FIGURE 2. Universal property of pushout square

*Proof.* As for notation, given any ring homomorphism  $h: A \longrightarrow B$  we let  $h_*$  stand for the functor  $- \otimes_A B$ . — To prove the Proposition we verify that the square has the universal property of a pushout, see Fig. 2. Let  $\alpha: \Sigma^{-1}K \longrightarrow T$  and  $\beta: S \longrightarrow T$  be ring homomorphisms such that  $\alpha \lambda_\Sigma = \beta f$ . Given a map  $\sigma: P \longrightarrow Q$  in  $\Sigma$  we know that

$$\beta_* f_*(\sigma) = (\beta f)_*(\sigma) = (\alpha \lambda_\Sigma)_*(\sigma) = \alpha_*(\lambda_\Sigma)_*(\sigma);$$

as  $(\lambda_\Sigma)_*(\sigma)$  is invertible so is  $\beta_* f_*(\sigma)$ . Hence the map  $\beta$  is  $f_*(\Sigma)$ -inverting, and consequently factorises uniquely as  $\beta = v \lambda_{f_*(\Sigma)}$ , for some ring homomorphism  $v: f_*(\Sigma)^{-1}S \longrightarrow T$ . From the chain of equalities

$$v \bar{f} \lambda_\Sigma = v \lambda_{f_*(\Sigma)} f = \beta f = \alpha \lambda_\Sigma$$

we conclude that  $\alpha = v \bar{f}$  since  $\lambda_\Sigma$  is an epimorphism by Proposition 4.1 (2).  $\square$

The following purely category-theoretic lemma will be applied, in the proof of Proposition 10.8, in the context of strongly graded rings and non-commutative localisation.

**Lemma 4.3.** *Suppose that we are given a commutative pushout square*

$$\begin{array}{ccc} A & \xrightarrow{\alpha} & B \\ \beta \downarrow & \lrcorner & \delta \downarrow \\ C & \xrightarrow{\gamma} & D \end{array}$$

(in any category) with  $\beta$  an epimorphism. Suppose further that there exists  $\iota: C \longrightarrow B$  with  $\iota\beta = \alpha$ . Then  $\delta\iota = \gamma$ , and  $\delta$  is an isomorphism.

*Proof.* First, since  $\delta\iota\beta = \delta\alpha = \gamma\beta$ , and since  $\beta$  is an epimorphism, we have  $\delta\iota = \gamma$ . Next, by the universal property of pushouts there exists a (uniquely determined) morphism  $\varphi: D \longrightarrow B$  with  $\varphi\delta = \text{id}_B$  and  $\varphi\gamma = \iota$ . The commutative diagram of Fig. 3 can be completed along the dotted arrow by both  $\text{id}_D$  and  $\delta\varphi$ ; by uniqueness, this means  $\delta\varphi = \text{id}_D$ .  $\square$

FIGURE 3. Pushout diagram used in proof of Lemma 4.3

## Part 2. $\mathbb{N}$ -graded rings and complexes contractible over $R_0$

For this part we assume that  $R = R_*[t, t^{-1}]$  is an arbitrary  $\mathbb{Z}$ -graded ring; in fact, we are only interested in the subring  $R_*[t] = \bigoplus_{k=0}^{\infty} R_k$  which is, in effect, an arbitrary  $\mathbb{N}$ -graded ring.

### 5. COMPLEXES CONTRACTIBLE OVER $R_0$

We characterise complexes  $C$  of  $R_*[t]$ -modules such that  $C \otimes_{R_*[t]} R_0$  is contractible, where the tensor product is taken *via* the “constant coefficient” ring homomorphism  $\text{tr}^0: t \mapsto 0$  of (1.3).

**The map  $\zeta$ .** Let  $M$  be an  $R_*[t]$ -module. Using the notation from (1.1), we write  $\zeta_M = \zeta$  for the obvious map of  $R_*[t]$ -modules

$$\zeta_M = \zeta : M \otimes_{R_*[t]} t^1 R_*[t] \longrightarrow M \otimes_{R_*[t]} t^0 R_*[t] = M, \quad m \otimes x \mapsto mx \quad (5.1)$$

induced by the inclusion map  $t^1 R_*[t] \longrightarrow t^0 R_*[t]$ . The map  $\zeta$  is to be thought of as a substitute for the action of the indeterminate  $t$ . More precisely, if  $R_*[t] = K[t]$  is a polynomial ring, then  $t^1 R_*[t] = tK[t]$  and the composition

$$M = M \otimes_{K[t]} K[t] \xrightarrow{\cong} M \otimes_{K[t]} (tK[t]) \xrightarrow{\zeta} M \otimes_{K[t]} K[t] = M,$$

where  $\tau(m \otimes r) = m \otimes tr$ , is given by  $m \mapsto mt$ ; that is, up to the isomorphism  $\tau$  the map  $\zeta$  coincides with the action of the indeterminate.

**Invertible matrices over  $R_*[[t]]$ .** We write an element  $z \in R_*[[t]]$  as a formal power series:  $z = \sum_{p \geq 0} z_p t^p$ . The usual proof shows that  $z$  is a unit in  $R_*[[t]]$  if and only if  $z_0 = \text{tr}^0(z)$  is a unit in  $R_0$ , cf. (1.2).

A square matrix  $M$  with entries in  $R_*[[t]]$  can be written as a formal power series  $M = \sum_{p \geq 0} M_p t^p$  with matrices  $M_p$  having entries in  $R_p$ ; again, the usual proof shows that *the matrix  $M$  is invertible over  $R_*[[t]]$  if and only if  $M_0 = \text{tr}^0(M)$  is invertible over  $R_0$ .*

**Notation 5.2.** We let  $\tilde{\Omega}_+$  denote the set of all square matrices  $M$  with entries in  $R_*[t]$  such that  $\text{tr}^0(M)$  is an invertible matrix over  $R_0$ , that is, such that  $M$  is invertible over  $R_*[[t]]$ .

We apply Proposition 4.1 (3) to the  $R_*[t]$ -ring  $f : R_*[t] \xrightarrow{c} R_*[[t]]$ :

**Lemma 5.3.** *A square matrix  $M$  with entries in the  $\mathbb{N}$ -graded ring  $R_*[t]$  becomes invertible in  $\tilde{\Omega}_+^{-1} R_*[t]$  if and only if  $\text{tr}^0(M)$  is invertible over  $R_0$ .  $\square$*

**The localisation  $\tilde{\Omega}_+^{-1} R_*[t]$ .** We consider an element  $A^+ \in \tilde{\Omega}_+$  of size  $k$  as an endomorphism  $A^+ : R_*[t]^k \longrightarrow R_*[t]^k$  of the finitely generated free  $R_*[t]$ -module  $R_*[t]^k$ . The non-commutative localisation

$$\lambda = \lambda_{\tilde{\Omega}_+} : R_*[t] \longrightarrow \tilde{\Omega}_+^{-1} R_*[t]$$

can be used to characterise the  $R_0$ -contractible complexes  $C^+$  as follows, generalising known results for polynomial rings (RANICKI [Ran98, Proposition 10.13]):

**Theorem 5.4.** *Let  $R_*[t] = \bigoplus_{k=0}^{\infty} R_k$  be an arbitrary  $\mathbb{N}$ -graded ring, and let  $C^+$  be a bounded complex of finitely generated free  $R_*[t]$ -modules. The following statements are equivalent:*

- (1) The complex  $C^+ \otimes_{R_*[t]} R_0$  is contractible, the tensor product being taken with respect to the ring map  $\text{tr}^0: R_*[t] \longrightarrow R_0$ ,  $t \mapsto 0$ .
- (2) The induced complex  $C^+ \otimes_{R_*[t]} R_*[[t]]$  is contractible.
- (3) The induced complex  $C^+ \otimes_{R_*[t]} \tilde{\Omega}_+^{-1} R_*[t]$  is contractible.
- (4) The map  $\zeta: C \otimes_{R_*[t]} t^1 R_*[t] \longrightarrow C \otimes_{R_*[t]} t^0 R_*[t]$  from (5.1) is a quasi-isomorphism.

*Proof.* (3)  $\Rightarrow$  (2)  $\Rightarrow$  (1): This follows from the factorisation

$$R_*[t] \xrightarrow{\subseteq} \tilde{\Omega}_+^{-1} R_*[t] \longrightarrow R_*[[t]] \xrightarrow{\text{tr}^0: t \mapsto 0} R_0$$

of the ring homomorphism  $\text{tr}^0: R_*[t] \longrightarrow R_0$ .

(1)  $\Rightarrow$  (3): We equip the finitely generated free modules  $C_n^+$  with arbitrary finite bases; denote the number of elements of the basis for  $C_n^+$  by  $r_n$  so that  $C_n^+$  is identified with  $R_*[t]^{r_n}$ . The differentials  $d_n^+: C_n^+ \longrightarrow C_{n-1}^+$  are thus represented by matrices  $D_n^+$  of size  $r_{n-1} \times r_n$  with entries in  $R_*[t]$ . The differentials  $\text{tr}^0(d_n^+)$  in the induced complex  $C^+ \otimes_{R_*[t]} R_0$  are then represented by the matrices  $\text{tr}^0(D_n^+)$ , identifying  $C_n^+ \otimes_{R_*[t]} R_0$  with  $R_0^{r_n}$ . By hypothesis there exists a contracting homotopy consisting of a family of  $R_0$ -linear maps

$$\sigma_n^+: C_n^+ \otimes_{R_*[t]} R_0 \longrightarrow C_{n+1}^+ \otimes_{R_*[t]} R_0$$

such that

$$\text{tr}^0(d_{n+1}^+) \circ \sigma_n^+ + \sigma_{n-1}^+ \circ \text{tr}^0(d_n^+) = \text{id}.$$

The map  $\sigma_n^+$  is represented by a matrix  $S_n^+$  of size  $r_{n+1} \times r_n$  with entries in  $R_0$ . The matrices satisfy the relation

$$\text{tr}^0(D_{n+1}^+ \circ S_n^+ + S_{n-1}^+ \circ D_n^+) = \text{tr}^0(D_{n+1}^+) \circ S_n^+ + S_{n-1}^+ \circ \text{tr}^0(D_n^+) = I_{r_n},$$

a unit matrix of size  $r_n$ . This implies, by Lemma 5.3, that the matrix

$$D_{n+1}^+ \circ S_n^+ + S_{n-1}^+ \circ D_n^+$$

becomes invertible over  $\tilde{\Omega}_+^{-1} R_*[t]$ . Thus the  $S_n^+$  define a  $\lambda_{\tilde{\Omega}_+}$ -proto-contraction of  $C^+$ , cf. §3. With Lemma 3.1 we conclude that  $C^+ \otimes_{R_*[t]} \tilde{\Omega}_+^{-1} R_*[t]$  is contractible as advertised.

(1)  $\Leftrightarrow$  (4): From the short exact sequence

$$\begin{aligned} 0 \longrightarrow C^+ \otimes_{R_*[t]} t^1 R_*[t] &\xrightarrow{\zeta} C^+ \otimes_{R_*[t]} t^0 R_*[t] \\ &\longrightarrow C^+ \otimes_{R_*[t]} R_0 \longrightarrow 0 \end{aligned}$$

we infer that the canonical map  $\text{cone}(\zeta) \longrightarrow C^+ \otimes_{R_*[t]} R_0$  is a quasi-isomorphism. Thus  $\zeta$  is a quasi-isomorphism if and only if  $\text{cone}(\zeta)$  is

acyclic if and only if  $C^+ \otimes_{R_*[t]} R_0$  is acyclic; as the latter complex consists of projective  $R_0$ -modules, this is equivalent with  $C^+ \otimes_{R_*[t]} R_0$  being contractible.  $\square$

**Theorem 5.5** (Universal property of  $\tilde{\Omega}_+^{-1}R_*[t]$ ). *Let  $R_*[t]$  be an arbitrary  $\mathbb{N}$ -graded ring. The localisation  $\lambda: R_*[t] \longrightarrow \tilde{\Omega}_+^{-1}R_*[t]$  is the universal  $R_*[t]$ -ring making  $R_0$ -contractible chain complexes contractible. That is, suppose that  $f: R_*[t] \longrightarrow S$  is an  $R_*[t]$ -ring such that for every bounded complex of finitely generated free  $R_*[t]$ -modules  $C^+$ , contractibility of  $C^+ \otimes_{R_*[t]} R_0$  implies contractibility of  $C^+ \otimes_{R_*[t]} S$ . Then there is a factorisation*

$$R_*[t] \xrightarrow{\lambda} \tilde{\Omega}_+^{-1}R_*[t] \xrightarrow{\eta} S$$

of  $f$ , with a uniquely determined ring homomorphism  $\eta$ .

*Proof.* It was shown in Theorem 5.4 that the  $R_*[t]$ -ring  $\tilde{\Omega}_+^{-1}R_*[t]$  makes  $R_0$ -contractible chain complexes contractible. Thus it is enough to verify that  $f$  is  $\tilde{\Omega}_+$ -invertible; the universal property of non-commutative localisation then yields the desired factorisation and its uniqueness. Consider the element  $A^+ \in \tilde{\Omega}_+$  as a chain complex

$$C^+ = (R_*[t]^k \xrightarrow{A^+} R_*[t]^k).$$

As  $A^+$  becomes invertible over  $\tilde{\Omega}_+^{-1}R_*[t]$ , the complex  $C^+ \otimes_{R_*[t]} \tilde{\Omega}_+^{-1}R_*[t]$  is contractible, hence so is  $C^+ \otimes_{R_*[t]} R_0$  by Theorem 5.4. This makes  $C^+ \otimes_{R_*[t]} S$  contractible, by hypothesis on  $f$ , whence  $A^+$  becomes invertible in  $S$  as required.  $\square$

### Part 3. Strongly graded rings and finite domination

We now turn to the theory of  $R_0$ -finite domination of  $R_*[t]$ -module complexes. We characterise finite domination *via* NOVIKOV homology (Theorem 8.1) and *via* a non-commutative localisation of  $R_*[t]$  (Theorem 10.6). We assume throughout that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring.

#### 6. ALGEBRAIC HALF-TORI AND THE MATHER TRICK

**Algebraic half-tori and the MATHER trick.** Let  $1 = \sum_j \alpha_j^{(1)} \beta_j^{(-1)}$  be a partition of unity of type  $(1, -1)$  in  $R = R_*[t, t^{-1}]$ . Given an arbitrary

$R_*[t]$ -module  $M$ , let  $\mu = \mu_M$  denote the map

$$\mu: M \otimes_{R_0} t^1 R_*[t] \longrightarrow M \otimes_{R_0} t^0 R_*[t], \quad m \otimes x \mapsto \sum_j m \alpha_j^{(1)} \otimes \beta_j^{(-1)} x. \quad (6.1)$$

The map  $\mu$  is  $R_0$ -balanced (hence well-defined) and independent of the choice of partition of unity since it can be written as the composition

$$\begin{aligned} M \otimes_{R_0} t^1 R_*[t] &\cong M \otimes_{R_0} R_0 \otimes_{R_0} t^1 R_*[t] \\ &\cong M \otimes_{R_0} R_1 \otimes_{R_0} R_{-1} \otimes_{R_0} t^1 R_*[t] \longrightarrow M \otimes_{R_0} t^0 R_*[t] \end{aligned}$$

where the second isomorphism is induced by  $\pi_1^{-1}: R_0 \xrightarrow{\cong} R_1 \otimes_{R_0} R_{-1}$ , cf. Lemma 2.2, and the last arrow is induced by the multiplication maps  $M \otimes_{R_0} R_1 \longrightarrow M$  and  $R_{-1} \otimes_{R_0} t^1 R_*[t] \longrightarrow t^0 R_*[t]$ .

As a matter of notation, we also introduce the inclusion map

$$\iota: M \otimes_{R_0} t^1 R_*[t] \longrightarrow M \otimes_{R_0} t^0 R_*[t], \quad m \otimes x \mapsto m \otimes x.$$

Moreover, it is convenient at this point to choose, once and for all, additional partitions of unity

$$1 = \sum_{j_n} \alpha_{j_n}^{(n)} \beta_{j_n}^{(-n)}$$

of type  $(n, -n)$ , for all  $n \geq 0$  ( $n \neq 1$ ). These exist in view of our standing assumption for this part, that the ring  $R = R_*[t, t^{-1}]$  is strongly graded.

**Lemma 6.2** (Canonical resolution). *Suppose that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring. Let  $M$  be a right  $R_*[t]$ -module. There is a short exact sequence of  $R_*[t]$ -modules*

$$0 \longrightarrow M \otimes_{R_0} t^1 R_*[t] \xrightarrow{\iota - \mu} M \otimes_{R_0} t^0 R_*[t] \xrightarrow{\pi} M \longrightarrow 0, \quad (6.3)$$

where  $\mu$  is as in (6.1),  $\iota(m \otimes x) = m \otimes x$  and  $\pi(m \otimes x) = mx$ .

*Proof.* This is similar to the proof of Proposition 3.2 in [HS17]. Since  $\sum_j \alpha_j^{(1)} \beta_j^{(-1)} = 1$  we have  $\pi \iota = \pi \mu$  and hence  $\pi(\iota - \mu) = 0$ . It is thus enough to show that the sequence is split exact when considered as a sequence of  $R_0$ -modules.

To begin with, the map  $\sigma(m) = m \otimes 1$  is certainly an  $R_0$ -linear section of  $\pi$ . Next, we define the  $R_0$ -linear map

$$\rho: M \otimes_{R_0} t^0 R_*[t] \longrightarrow M \otimes_{R_0} t^1 R_*[t]$$

on elements of the form  $m \otimes x_d$ , with  $x_d \in R_d$ , by the formula

$$\rho(m \otimes x_d) = \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d .$$

We note the particular cases

$$\begin{aligned} \rho(m \otimes x_0) &= 0 , \\ \rho(m \otimes x_1) &= m \otimes x_1 , \\ \rho(m \otimes x_2) &= m \otimes x_2 + \sum_j m \alpha_j^{(1)} \otimes \beta_j^{(-1)} x_2 . \end{aligned}$$

The summands  $s_k = \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d$ , and hence the map  $\rho$ , do not depend on the particular choice of partition of unity. This is because  $s_k$  is the image of  $m \otimes x_d$  under the the composition

$$\begin{aligned} M \otimes_{R_0} R_d &\cong M \otimes_{R_0} R_0 \otimes_{R_0} R_d \\ &\xrightarrow[\cong]{\pi_k^{-1}} M \otimes_{R_0} R_k \otimes_{R_0} R_{-k} \otimes_{R_0} R_d \xrightarrow{\sigma} M \otimes_{R_0} R_{-k+d} , \end{aligned}$$

where  $\sigma(m \otimes a \otimes b \otimes x) = ma \otimes bx$ , and  $\pi_k^{-1}$  does not depend on choices by Lemma 2.2.

We have  $\rho \circ (\iota - \mu) = \text{id}$  since, for an element  $x_d \in R_d$ , we calculate

$$\begin{aligned} \rho \circ (\iota - \mu)(m \otimes x_d) &= \rho(m \otimes x_d) - \sum_j \rho(m \alpha_j^{(1)} \otimes \beta_j^{(-1)} x_d) \\ &= \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d - \sum_{k=0}^{d-2} \sum_{j_k} \sum_j m \alpha_j^{(1)} \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} \beta_j^{(-1)} x_d \\ &\stackrel{(\diamond)}{=} \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d - \sum_{k=0}^{d-2} \sum_{j_{k+1}} m \alpha_{j_{k+1}}^{(k+1)} \otimes \beta_{j_{k+1}}^{(-k-1)} x_d \\ &= \sum_{j_0} m \alpha_{j_0}^{(0)} \otimes \beta_{j_0}^{(0)} x_d = \sum_{j_0} m \alpha_{j_0}^{(0)} \beta_{j_0}^{(0)} \otimes x_d = m \otimes x_d ; \end{aligned}$$

the equality labelled  $(\diamond)$  makes use of Lemma 2.3, and of the fact that summands of the form  $s_{k+1}$  do not depend on choice of the partition of unity involved so that

$$\sum_{j_k} \sum_j m \alpha_j^{(1)} \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} \beta_j^{(-1)} x_d = s_{k+1} = \sum_{j_{k+1}} m \alpha_{j_{k+1}}^{(k+1)} \otimes \beta_{j_{k+1}}^{(-k-1)} x_d .$$

It remains to verify the equality  $\sigma \circ \pi + (\iota - \mu) \circ \rho = \text{id}$ . For this, let  $x \in R_d$  and  $m \in M$ , and calculate:

$$\begin{aligned}
(\iota - \mu) \circ \rho(m \otimes x_d) &= (\iota - \mu) \left( \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d \right) \\
&= \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d - \sum_j \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \alpha_j^{(1)} \otimes \beta_j^{(-1)} \beta_{j_k}^{(-k)} x_d \\
&\stackrel{(\diamond)}{=} \sum_{k=0}^{d-1} \sum_{j_k} m \alpha_{j_k}^{(k)} \otimes \beta_{j_k}^{(-k)} x_d - \sum_{k=0}^{d-1} \sum_{j_{k+1}} m \alpha_{j_{k+1}}^{(k+1)} \otimes \beta_{j_{k+1}}^{(-k-1)} x_d \\
&= \sum_{j_0} m \alpha_{j_0}^{(0)} \otimes \beta_{j_0}^{(-0)} x_d - \sum_{j_d} m \alpha_{j_d}^{(d)} \otimes \beta_{j_d}^{(-d)} x_d \\
&= \sum_{j_0} m \alpha_{j_0}^{(0)} \beta_{j_0}^{(-0)} \otimes x_d - \sum_{j_d} m \alpha_{j_d}^{(d)} \beta_{j_d}^{(-d)} x_d \otimes 1 \\
&= m \otimes x_d - m x_d \otimes 1 = (\text{id} - \sigma \circ \pi)(m \otimes x_d).
\end{aligned}$$

(As before, the equality marked  $(\diamond)$  holds because summands of the form  $s_{k+1}$  do not depend on choice of the partition of unity involved.) This finishes the proof.  $\square$

**Definition 6.4.** Let  $C^+$  be a complex of  $R_*[t]$ -modules. The mapping cone  $\mathfrak{H}^+(C^+)$  of the map  $\iota - \mu$ ,

$$\mathfrak{H}^+(C^+) = \text{cone} \left( C^+ \otimes_{R_0} t^1 R_*[t] \xrightarrow{\iota - \mu} C^+ \otimes_{R_0} t^0 R_*[t] \right),$$

is called the *algebraic half-torus* of  $C^+$ .

**Corollary 6.5.** Let  $C^+$  be a complex of  $R_*[t]$ -modules. The canonical map

$$\mathfrak{H}^+(C^+) = \text{cone} \left( C^+ \otimes_{R_0} t^1 R_*[t] \xrightarrow{\iota - \mu} C^+ \otimes_{R_0} t^0 R_*[t] \right) \longrightarrow C^+$$

induced by the short exact sequence (6.3) is a quasi-isomorphism. If  $C^+$  is bounded below and consists of projective  $R_*[t]$ -modules, the map is a homotopy equivalence of  $R_*[t]$ -module complexes.

*Proof.* This is a direct consequence of standard homological algebra and Lemma 6.2 above.  $\square$

The following result, though technical, is central to the theory of finite domination. By the previous Corollary we can replace any complex  $C^+$  of  $R_*[t]$ -modules by an algebraic half-torus, up to quasi-isomorphism; the MATHER trick is the observation that we can further replace the complex  $C^+$  within the mapping cone of the half-torus construction by an  $R_0$ -module complex homotopy equivalent to  $C^+$ .

**Proposition 6.6** (The algebraic MATHER trick for algebraic half-tori). *Let  $R = R_*[t, t^{-1}]$  be a strongly  $\mathbb{Z}$ -graded ring, let  $C^+$  be a complex of*

$R_*[t]$ -modules, and let  $D$  be a complex of  $R_0$ -modules. Let  $\alpha: C^+ \longrightarrow D$  and  $\beta: D \longrightarrow C^+$  be mutually inverse chain homotopy equivalences of  $R_0$ -module complexes with  $H: \text{id} \simeq \alpha\beta$  a specified homotopy. Write  $\psi$  for the  $R_*[t]$ -module complex map

$$\psi = (\alpha \otimes \text{id}) \circ (\iota - \mu) \circ (\beta \otimes \text{id}): D \otimes_{R_0} t^1 R_*[t] \longrightarrow D \otimes_{R_0} t^0 R_*[t].$$

Then the square diagram (6.7) in Fig. 4 commutes up to a preferred homotopy  $J$  induced by  $H$ , given by the formula

$$J = (\alpha \otimes \text{id}) \circ (\iota - \mu) \circ (H \otimes \text{id}): (\alpha \otimes \text{id}) \circ (\iota - \mu) \simeq \psi \circ (\alpha \otimes \text{id}).$$

The homotopy  $J$  induces a preferred chain map

$$\Xi: \mathfrak{H}^+(C^+) = \text{cone}(\iota - \mu) \longrightarrow \text{cone}(\psi)$$

which is a quasi-isomorphism. If both  $C^+$  and  $D$  are bounded below complexes of projective  $R_0$ -modules, the map  $\mathfrak{H}^+(C^+) \longrightarrow \text{cone}(\psi)$  is a homotopy equivalence of  $R_*[t]$ -module complexes.

$$\begin{array}{ccc} C^+ \otimes_{R_0} t^1 R_*[t] & \xrightarrow{\iota - \mu} & C^+ \otimes_{R_0} t^0 R_*[t] \\ \alpha \otimes \text{id} \downarrow & & \alpha \otimes \text{id} \downarrow \\ D \otimes_{R_0} t^1 R_*[t] & \xrightarrow{\psi} & D \otimes_{R_0} t^0 R_*[t] \end{array} \quad (6.7)$$

FIGURE 4. The MATHER trick square

*Proof.* By construction,  $J$  is a homotopy from  $(\alpha \otimes \text{id}) \circ (\iota - \mu)$  to  $\psi \circ (\alpha \otimes \text{id})$ . Hence we obtain a chain map of the mapping cones of the horizontal maps in the diagram,

$$\alpha_* = \begin{pmatrix} \alpha \otimes \text{id} & 0 \\ J & \alpha \otimes \text{id} \end{pmatrix}: \mathfrak{H}^+(C^+) = \text{cone}(\iota - \mu) \longrightarrow \text{cone}(\psi);$$

this map is a quasi-isomorphism since  $\alpha$  is a homotopy equivalence (so the induced map on homology will be represented by a lower triangular matrix with isomorphisms on the main diagonal).  $\square$

**Corollary 6.8.** *If  $C^+$  is an  $R_0$ -finitely dominated bounded below chain complex of projective  $R_*[t]$ -modules, then  $C^+$  is  $R_*[t]$ -finitely dominated, that is,  $C^+$  is homotopy equivalent to a bounded complex of finitely generated projective  $R_*[t]$ -modules.*

*Proof.* As  $C^+$  is  $R_0$ -finitely dominated we can choose an  $R_0$ -linear chain homotopy equivalence  $\alpha: C^+ \longrightarrow D$  from  $C^+$  to a bounded complex  $D$

of finitely generated projective  $R_0$ -modules. By Corollary 6.5 and Proposition 6.6 there are quasi-isomorphisms

$$C^+ \xleftarrow{\cong} \mathfrak{H}^+(C^+) \xrightarrow{\cong} \text{cone}(\psi) \quad (6.9)$$

with  $\psi: D \otimes_{R_0} t^1 R_*[t] \longrightarrow D \otimes_{R_0} t^0 R_*[t]$  as defined in Proposition 6.6 a map of bounded complexes of finitely generated projective  $R_*[t]$ -modules. It follows that  $C^+$  is quasi-isomorphic, hence homotopy equivalent, to a bounded complex of finitely generated projective  $R_*[t]$ -modules as claimed.  $\square$

## 7. FINITE DOMINATION AND HOMOTOPY FINITENESS

It is an interesting question whether in the situation of Corollary 6.8 the complex  $C^+$  is actually  $R_*[t]$ -homotopy finite, that is, homotopy equivalent to a bounded complex of finitely generated free  $R_*[t]$ -modules. In general this turns out to be false; however, when working with  $R_*[t, t^{-1}]$  instead of  $R_*[t]$  the analogous question has a positive answer. — As before, let  $R = R_*[t, t^{-1}]$  be a strongly  $\mathbb{Z}$ -graded ring.

**Proposition 7.1.** *Suppose that  $C$  is a bounded complex of finitely generated projective  $R_*[t, t^{-1}]$ -modules. If  $C$  is  $R_0$ -finitely dominated, then  $C$  is  $R_*[t, t^{-1}]$ -homotopy finite, i.e.,  $C$  is homotopy equivalent to a bounded complex of finitely generated free  $R_*[t, t^{-1}]$ -modules.*

*Proof.* Let  $D$  be a bounded chain complex of finitely generated projective  $R_0$ -modules chain homotopy equivalent to  $C$ . Then by the MATHER trick for algebraic tori [HS17, Lemma 3.7],  $C$  is homotopy equivalent, as an  $R_*[t, t^{-1}]$ -module complex, to the mapping cone of a certain self map of the induced complex  $D \otimes_{R_0} R_*[t, t^{-1}]$ . Hence the finiteness obstruction of  $C$  in  $\tilde{K}_0(R_*[t, t^{-1}])$  vanishes whence  $C$  is  $R_*[t, t^{-1}]$ -homotopy finite.  $\square$

The analogous statement holds over a polynomial ring  $R_0[t]$  with a central indeterminate  $t$ : An  $R_0$ -finitely dominated, bounded  $R_0[t]$ -module complex  $C^+$  of finitely generated projective modules is  $R_0[t]$ -homotopy finite. For  $C^+ \simeq \text{cone}(\psi)$  as in (6.9) and (6.7), and the finiteness obstruction of the mapping cone vanishes since  $tR_0[t] \cong R_0[t]$ . — In general, however, this line of reasoning fails when working over  $R_*[t]$ .

**Example 7.2.** *There exist a strongly  $\mathbb{Z}$ -graded ring  $R = R_*[t, t^{-1}]$  together with a bounded complex  $C^+$  of finitely generated projective  $R_*[t]$ -modules such that  $C^+$  is  $R_0$ -finitely dominated but not homotopy equivalent to a*

bounded complex of finitely generated free  $R_*[t]$ -modules. Specifically<sup>1</sup>, let  $K$  be a field and let  $R = R_*[t, t^{-1}]$  be the LEAVITT  $K$ -algebra of type  $(1, 1)$ , that is, the (non-commutative)  $K$ -algebra on generators  $A, B, C, D$  subject to the relations

$$AB + CD = 1, \quad BA = DC = 1, \quad BC = DA = 0;$$

we declare that  $A$  and  $C$  have degree  $-1$ , while  $B$  and  $D$  are given degree  $1$ . This is a  $\mathbb{Z}$ -graded ring since all relations are homogeneous of degree  $0$ . It is strongly graded by Corollary 2.4 as the relations  $AB + CD = 1$  and  $BA = 1$  provide partitions of unity of types  $(-1, 1)$  and  $(1, -1)$ , respectively. It is known that  $R_0$  can be identified with an increasing union  $\bigcup_{n \geq 0} \mathbf{Mat}_{2^n}(K)$  of matrix algebras, using the block-diagonal embeddings  $x \mapsto \begin{pmatrix} x & 0 \\ 0 & x \end{pmatrix}$ . It follows that  $R_0$  has IBN, and since the projection map  $R_*[t] = \bigoplus_{k \geq 0} R_k \longrightarrow R_0$  is a ring homomorphism, so does  $R_*[t]$ . — The  $R_*[t]$ -module  $Q = t^1 R_*[t]$  is finitely generated projective by Corollary 2.8 (3), and the map

$$R_*[t] \xrightarrow{\cong} Q \oplus Q, \quad r \mapsto (Br, Dr) \quad (7.3)$$

is an isomorphism of  $R_*[t]$ -modules with inverse  $(x, y) \mapsto Ax + Cy$ . In addition,  $Q$  is not stably free: if  $Q \oplus R_*[t]^m \cong R_*[t]^n$ , then by (7.3) also

$$R_*[t]^{2n} \cong (Q \oplus R_*[t]^m) \oplus (Q \oplus R_*[t]^m) \cong R_*[t]^{2m+1};$$

as  $R_*[t]$  has IBN, the inequality  $2n \neq 2m + 1$  renders this impossible. The class of  $Q$  in  $\tilde{K}_0(R_*[t])$  is thus non-zero, and has in fact order 2 in view of the isomorphism (7.3). Thus the inclusion map  $Q \longrightarrow R_*[t]$ , considered as a chain complex  $C^+$ , is an example of a bounded complex of finitely generated projective  $R_*[t]$ -modules not homotopy equivalent to a bounded complex of finitely generated free  $R_*[t]$ -modules. On the other hand, the complex  $C^+$  is certainly  $R_0$ -finitely dominated since the cokernel of the inclusion map  $Q = t^1 R_*[t] \longrightarrow R_*[t]$  is isomorphic to  $R_0$ .

## 8. $R_0$ -FINITE DOMINATION OF $R_*[t]$ -MODULE COMPLEXES

We now develop a homological criterion to detect if a chain complex  $C^+$  of  $R_*[t]$ -modules is  $R_0$ -finitely dominated when considered as a complex of  $R_0$ -modules *via* restriction of scalars. This happens if and only if  $C^+$  has trivial NOVIKOV homology in the sense that the induced chain complex  $C^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is acyclic.

---

<sup>1</sup>I am indebted to R. Hazrat for bringing this example to my attention.

**Theorem 8.1.** *Let  $R = R_*[t, t^{-1}]$  be a strongly  $\mathbb{Z}$ -graded ring, and let  $C^+$  be a bounded chain complex of finitely generated projective  $R_*[t]$ -modules. The following statements are equivalent:*

- (1) *The complex  $C^+$  is  $R_0$ -finitely dominated.*
- (2) *The complex  $C^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is contractible (i.e.,  $C^+$  has trivial NOVIKOV homology).*

*Proof.* (1)  $\Rightarrow$  (2): As  $C^+$  is  $R_0$ -finitely dominated, we find a bounded complex  $D$  of finitely generated projective  $R_0$ -modules, and mutually inverse  $R_0$ -linear chain homotopy equivalences  $\alpha: C^+ \longrightarrow D$  and  $\beta: D \longrightarrow C^+$ . Let  $\psi$  be as in Proposition 6.6; together with Corollary 6.5, the MATHER trick asserts that the  $R_*[t]$ -module complexes  $C^+$  and  $\text{cone}(\psi)$  are quasi-isomorphic and thus are chain homotopy equivalent (as both are bounded below and consist of projective  $R_*[t]$ -modules). Thus  $C^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is homotopy equivalent to  $\text{cone}(\psi) \otimes_{R_*[t]} R_*((t^{-1}))$ . The latter complex in turn is isomorphic to the mapping cone of the chain map

$$D \otimes_{R_0} R_*((t^{-1})) \longrightarrow D \otimes_{R_0} R_*((t^{-1}))$$

sending the element  $x \otimes \sum_{i \leq k} r_i t^i$  to

$$\alpha\beta(x) \otimes \sum_{j \leq k} r_j t^j - \sum_j \alpha(\beta(x)\alpha_j^{(1)}) \otimes \sum_{j \leq k} \beta_j^{(-1)} r_j t^{j-1},$$

where we write elements of  $R_*((t^{-1}))$  as formal LAURENT series in  $t^{-1}$ ; note that in the target of the map,  $\beta_j^{(-1)} r_j$  is the coefficient of  $t^{j-1}$  as  $\beta_j^{(-1)}$  has degree  $-1$ .

As  $D$  consists of finitely presented  $R_0$ -modules, we can identify both the tensor products

$$D \otimes_{R_0} R_*[t] \otimes_{R_*[t]} R_*((t^{-1})) = D \otimes_{R_0} R_*((t^{-1}))$$

and

$$D \otimes_{R_0} t^1 R_*[t] \otimes_{R_*[t]} R_*((t^{-1})) = D \otimes_{R_0} R_*((t^{-1}))$$

with the twisted right-truncated power of  $D$  [HS17, Proposition 3.13], that is,

$$D \otimes_{R_0} R_*((t^{-1})) \cong \prod_{n \leq 0} (D \otimes_{R_0} R_n) \oplus \bigoplus_{n > 0} (D \otimes_{R_0} R_n).$$

Thus we rewrite  $\text{cone}(\psi) \otimes_{R_*[t]} R_*((t^{-1}))$  as the right-truncated totalisation [Hüt11, Definition 1.1] of a double complex

$$Z_{p,q} = (D_{p+q+1} \otimes_{R_0} R_p) \oplus (D_{p+q} \otimes_{R_0} R_p)$$

with vertical differential  $d^v: Z_{p,q} \longrightarrow Z_{p,q-1}$  and horizontal differential  $d^h: Z_{p,q} \longrightarrow Z_{p-1,q}$  given by the formulæ

$$d^v(x \otimes a, y \otimes b) = (-d(x) \otimes a, \alpha\beta(x) \otimes a + d(y) \otimes b),$$

$$d^h(x \otimes a, y \otimes b) = \left( -\sum \alpha(\beta(y)\alpha_j^{(1)}) \otimes \beta_j^{(-1)}b, 0 \right).$$

The symbol “ $d$ ”, without any decorations, refers to the differential of the chain complex  $D$ . The columns are acyclic since  $Z_{p,*}$  is a shift suspension of  $\text{cone}(\alpha\beta) \otimes_{R_0} R_p$  and the chain map  $\alpha\beta$  is homotopic to an identity map. It follows that  $C^+ \otimes_{R_*[t]} R_*((t^{-1})) \simeq \text{cone}(\psi) \otimes_{R_*[t]} R_*((t^{-1}))$  is acyclic [Hüt11, Proposition 1.2], and hence contractible.

(2)  $\Rightarrow$  (1): As  $C^+$  consists of finitely generated projective  $R_*[t]$ -modules, there exists another bounded complex  $B^+$  with zero differentials, consisting of finitely generated projective  $R_*[t]$ -modules, such that  $A^+ = B^+ \oplus C^+$  is a bounded complex of finitely generated free  $R_*[t]$ -modules. We equip  $A_k^+$  with a basis with  $r_k$  elements, and identify  $A_k^+$  with  $R_*[t]^{r_k}$  henceforth. The differential  $d_k: A_k^+ \longrightarrow A_{k-1}^+$  is thus represented by a matrix  $D_k$  with entries in  $R_*[t]$ .

Suppose, for ease of notation, that  $C^+$  is concentrated in chain levels between 0 and  $m$ . We can choose integers

$$d_m \leq d_{m-1} \leq \dots \leq d_0 = -1$$

so that  $D_k$  defines a map  $d_k^-: t^{d_k} R_*[[t^{-1}]]^{r_k} \longrightarrow t^{d_{k-1}} R_*[[t^{-1}]]^{r_{k-1}}$ ; we only need to ensure that no entry of  $D_k$  has a non-zero homogeneous component of degree exceeding  $d_{k-1} - d_k$ . We let  $S$  denote the chain complex thus defined, with  $S_k = t^{d_k} R_*[[t^{-1}]]^{r_k}$  and differentials  $D_k$ . Similarly, we let  $N$  denote the chain complex with  $N_k = R_*((t^{-1}))^{r_k}$  and differentials  $D_k$ . Note that  $S$  is a subcomplex of  $N$ .

For any  $d \leq -1$  there is a short exact sequence of  $R_0$ -modules

$$0 \longrightarrow t^d R_*[[t^{-1}]] \oplus R_*[t] \xrightarrow{(-1 \ 1)} R_*((t^{-1})) \longrightarrow \bigoplus_{j=d+1}^{-1} R_j \longrightarrow 0 \quad (8.2)$$

with last term a finitely generated projective  $R_0$ -module by Corollary 2.8, as  $R_*[t, t^{-1}]$  is strongly graded. It follows that there is a short exact sequence of  $R_0$ -module complexes

$$0 \longrightarrow S \oplus A^+ \xrightarrow{\beta} N \longrightarrow P \longrightarrow 0 \quad (8.3)$$

with  $P$  a bounded complex of finitely generated projective  $R_0$ -modules. In chain degree  $k$  this sequence is actually just the  $r_k$ -fold direct sum of (8.2) with itself, for  $d = d_k$ .

From the sequence (8.3) we infer that the map from the mapping cone of  $\beta$  to  $P$  is a quasi-isomorphism. Now recall  $A^+ = B^+ \oplus C^+$  and observe the consequent splitting

$$N = A^+ \otimes_{R_*[t]} R_*((t^{-1})) = B^+ \otimes_{R_*[t]} R_*((t^{-1})) \oplus C^+ \otimes_{R_*[t]} R_*((t^{-1})). \quad (8.4)$$

By hypothesis  $C^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is contractible; thus  $N$  is quasi-isomorphic, via the projection map, to  $B^+ \otimes_{R_*[t]} R_*((t^{-1}))$ . As taking mapping cones is homotopy invariant, we can replace  $N$  by the latter complex and conclude that  $P$  is quasi-isomorphic to the mapping cone of the map

$$\gamma: S \oplus A^+ = S \oplus B^+ \oplus C^+ \xrightarrow{(-1 \ 1 \ 0)} B^+ \otimes_{R_*[t]} R_*((t^{-1})).$$

As  $\gamma$  is the zero map on the  $C^+$ -summand, the mapping cone of  $\gamma$  contains  $C^+$  as a direct summand. Hence in the derived category of the ring  $R_0$ , the complex  $C^+$  is a retract of  $P$ . Since both complexes are bounded and consist of projective  $R_0$ -modules, we conclude that  $C^+$  is a retract up to homotopy of  $P$  whence  $C^+$  is  $R_0$ -finitely dominated as claimed.  $\square$

## 9. $R_*[t]$ -FREDHOLM MATRICES

Let  $R = R_*[t, t^{-1}]$  be a  $\mathbb{Z}$ -graded ring, and let  $A^+$  be a non-zero square matrix of size  $k$  with entries in  $R_*[t, t^{-1}]$ . For suitable  $m \in \mathbb{Z}$ , multiplication by  $A^+$  defines an  $R_*[t]$ -module homomorphism

$$A^+ = \mu(A^+, m): R_*[t]^k \longrightarrow (t^{-m}R_*[t])^k, \quad x \mapsto A^+ \cdot x;$$

“suitable” means, in fact, that  $-m$  is not larger than the minimal degree of non-zero homogeneous components of entries of  $A^+$ . Suppose now that in addition to such  $m$  we fix an integer  $n > m$  so that the map  $\mu(A^+, n)$  is defined as well.

**Lemma 9.1.** *There is an isomorphism of  $R_0$ -modules*

$$\operatorname{coker} \mu(A^+, n) \cong \operatorname{coker} \mu(A^+, m) \oplus \bigoplus_{k=-n}^{-m-1} R_k.$$

*Proof.* The direct sum of the exact sequence of  $R_0$ -modules

$$R_*[t]^k \xrightarrow{\mu(A^+, m)} (t^{-m}R_*[t])^k \longrightarrow \operatorname{coker} \mu(A^+, m) \longrightarrow 0$$

with the exact sequence

$$0 \longrightarrow \bigoplus_{k=-n}^{-m-1} R_k \xrightarrow{=} \bigoplus_{k=-n}^{-m-1} R_k \longrightarrow 0$$

yields a new exact sequence, which is precisely the sequence

$$R_*[t]^k \xrightarrow{\mu(A^+, n)} (t^{-n}R_*[t])^k \longrightarrow \operatorname{coker} \mu(A^+, m) \oplus \bigoplus_{k=-n}^{-m-1} R_k \longrightarrow 0.$$

Hence  $\operatorname{coker} \mu(A^+, n) \cong \operatorname{coker} \mu(A^+, m) \oplus \bigoplus_{k=-n}^{-m-1} R_k$  as  $R_0$ -modules.  $\square$

**Corollary 9.2.** *Suppose that  $R = R_*[t, t^{-1}]$  is strongly  $\mathbb{Z}$ -graded. In the situation of Lemma 9.1, the module  $\operatorname{coker} \mu(A^+, n)$  is a finitely generated projective  $R_0$ -module if and only if  $\operatorname{coker} \mu(A^+, m)$  is.*

*Proof.* This is a consequence of Corollary 2.8 (1) and Lemma 9.1.  $\square$

**Proposition 9.3.** *Suppose that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring. Let  $A^+$  be a  $k \times k$ -matrix with entries in  $R_*[t, t^{-1}]$ , and let  $m \in \mathbb{Z}$  be “suitable” in the sense that multiplication by  $A^+$  yields a map of finitely generated projective  $R_*[t]$ -modules  $A^+ = \mu(A^+, m): R_*[t]^k \longrightarrow t^{-m}R_*[t]^k$ ,  $x \mapsto A^+ \cdot x$  (see discussion above) which we may consider as a chain complex concentrated in chain degrees 1 and 0. The following statements are equivalent:*

- (1) *The chain complex  $A^+$  is  $R_0$ -finitely dominated.*
- (2) *The induced chain complex  $A^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is contractible.*
- (3) *The map  $A^+$  is invertible over  $R_*((t^{-1}))$ , that is, the map*

$$R_*((t^{-1}))^k \longrightarrow R_*((t^{-1}))^k, \quad x \mapsto A^+ \cdot x$$

*is an isomorphism.*

- (4) *The matrix  $A^+$  is invertible in the ring of all square matrices of size  $k$  with entries in  $R_*((t^{-1}))$ .*
- (5) *The map  $\mu(A^+, m)$  is injective, and  $\operatorname{coker} \mu(A^+, m)$  is a finitely generated projective  $R_0$ -module.*

Moreover, the validity of these statements does not depend on the specific choice of a suitable  $m \in \mathbb{Z}$ .

**Definition 9.4.** A square matrix with entries in  $R_*[t, t^{-1}]$  satisfying one (and hence all) of the conditions listed in Proposition 9.3 is called an  $R_*[t]$ -FREDHOLM matrix. The set of all  $R_*[t]$ -FREDHOLM matrices (of arbitrary finite size) is denoted by the symbol  $\Omega_+$ .

*Proof of Proposition 9.3.* Condition (5) is insensitive to the precise value of the suitable integer  $m$ , in view of Corollary 9.2.

The equivalence of conditions (1) and (2) is Theorem 8.1 above. Statements (3) and (4) are trivially equivalent.

By Lemma 2.5, the multiplication map

$$t^{-m}R_*[t] \otimes_{R_*[t]} R_*[t, t^{-1}] \longrightarrow R_*[t, t^{-1}], \quad x \otimes y \mapsto xy$$

is an isomorphism of  $R_*[t, t^{-1}]$ -modules. It follows that there is a chain of isomorphisms

$$\begin{aligned} t^{-m}R_*[t] \otimes_{R_*[t]} R_*((t^{-1})) &\cong t^{-m}R_*[t] \otimes_{R_*[t]} R_*[t, t^{-1}] \otimes_{R_*[t, t^{-1}]} R_*((t^{-1})) \\ &\cong R_*[t, t^{-1}] \otimes_{R_*[t, t^{-1}]} R_*((t^{-1})) \cong R_*((t^{-1})) \end{aligned}$$

with composition the multiplication map. In view of this, statements (2) and (3) are equivalent.

If (5) holds then the chain complex  $A^+$  is  $R_0$ -homotopy equivalent to the module  $\text{coker } \mu(A^+, m)$ , considered as a chain complex concentrated in degree 0, which shows that (1) is satisfied in this case.

Suppose finally that (3) holds; we will show that (5) is valid as well. We infer from the commutative square

$$\begin{array}{ccc} R_*[t]^k & \xrightarrow{\mu(A^+, m)} & t^{-m}R_*[t]^k \\ \subset \downarrow & & \subset \downarrow \\ R_*((t^{-1}))^k & \xrightarrow[\cong]{A^+} & R_*((t^{-1}))^k \end{array}$$

that the map  $\mu(A^+, m)$  must be injective. Thus it remains to verify that  $\text{coker } \mu(A^+, m)$  is a finitely generated projective  $R_0$ -module. Assuming  $m \geq 1$ , as we may in view of Corollary 9.2, we can embed  $\mu(A^+, m)$  into a commutative diagram of  $R_0$ -modules

$$\begin{array}{ccccc} t^{-1}R[[t^{-1}]]^k & \xrightarrow{\subset} & R((t^{-1}))^k & \xleftarrow{\supset} & R_*[t]^k \\ A^+ \downarrow & & A^+ \downarrow & & A^+ \downarrow \mu(A^+, m) \\ t^q R[[t^{-1}]]^k & \xrightarrow{\subset} & R((t^{-1}))^k & \xleftarrow{\supset} & t^{-m}R_*[t]^k \end{array} \quad (9.5)$$

where  $q \geq 0$  is sufficiently large; it is sufficient that  $q$  exceeds the maximal degree of any non-zero homogeneous component of the entries of  $A^+$ .

Now in any ABELIAN category, a diagram  $\mathcal{D} = (X \xrightarrow{\xi} Y \xleftarrow{\zeta} Z)$  gives rise to an exact sequence, natural in  $\mathcal{D}$ , of the form

$$0 \longrightarrow \ker(\xi - \zeta) \longrightarrow X \oplus Z \xrightarrow{\xi - \zeta} Y \longrightarrow \text{coker}(\xi - \zeta) \longrightarrow 0.$$

We apply this to the rows of diagram (9.5) above, noting the the coker term is trivial in both cases (since  $q, m \geq 0$ ). The kernel, on the other hand, is trivial in case of the top row, and is the finitely generated projective  $R_0$ -module  $P = \bigoplus_{-m}^q R_j$  for the bottom row. We arrive at the following

commutative diagram with exact rows:

$$\begin{array}{ccccccc}
0 & \longrightarrow & t^{-1}R((t^{-1}))^k \oplus R_*[t]^k & \longrightarrow & R((t^{-1})) & \longrightarrow & 0 \\
& & \downarrow & & \downarrow & & \\
& & A^+ \oplus A^+ & & A^+ & & \\
& & \downarrow & & \downarrow & & \\
0 & \longrightarrow & P & \longrightarrow & t^q R((t^{-1}))^k \oplus t^{-m}R_*[t]^k & \longrightarrow & R((t^{-1})) \longrightarrow 0
\end{array}$$

As the right-hand vertical map is an isomorphism by hypothesis (3), the SNAKE lemma yields an isomorphism of  $P$  with the cokernel of the middle vertical map, which contains  $\text{coker } \mu(A^+, m): R_*[t]^k \longrightarrow t^{-m}R_*[t]^k$  as a direct summand. This shows that  $\text{coker } \mu(A^+, m)$  is a finitely generated projective  $R_0$ -module as desired.  $\square$

#### 10. THE FREDHOLM LOCALISATIONS $\Omega_+^{-1}R_*[t]$ AND $\Omega_+^{-1}R_*[t, t^{-1}]$

We now turn our attention to the non-commutative localisations

$$\alpha: R_*[t] \longrightarrow \Omega_+^{-1}R_*[t] \quad \text{and} \quad \gamma: R_*[t, t^{-1}] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$$

where  $\Omega_+$  denotes the set of  $R_*[t]$ -FREDHOLM matrices as in Definition 9.4. To be precise, we define  $\alpha = \lambda_{\Omega_+}: R_*[t] \longrightarrow \Omega_+^{-1}R_*[t]$  as the non-commutative localisation inverting all the maps

$$\mu(A^+, m): R_*[t]^k \longrightarrow t^{-m}R_*[t]^k \quad (10.1)$$

of finitely generated projective  $R_*[t]$ -modules, where  $k \geq 1$  is arbitrary,  $A^+ \in \Omega_+$  has size  $k$ , and  $m \in \mathbb{Z}$  is suitable in the sense of §9. As  $A^+$  satisfies property (4) of Proposition 9.3, the universal property of non-commutative localisation yields a factorisation

$$R_*[t] \xrightarrow{\alpha} \Omega_+^{-1}R_*[t] \longrightarrow R((t^{-1})) \quad (10.2)$$

of the inclusion map; in particular,  $\alpha$  is injective. — Similarly, we define  $\gamma = \lambda_{\Omega_+}: R_*[t, t^{-1}] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$  as the non-commutative localisation inverting all the maps

$$A^+: R_*[t, t^{-1}]^k \longrightarrow R_*[t, t^{-1}]^k \quad (10.3)$$

of finitely generated free  $R_*[t, t^{-1}]$ -modules, where  $k \geq 1$  is arbitrary and  $A^+ \in \Omega_+$  has size  $k$ . As  $A^+$  satisfies property (4) of Proposition 9.3, the universal property of non-commutative localisation yields a factorisation

$$R_*[t, t^{-1}] \xrightarrow{\gamma} \Omega_+^{-1}R_*[t, t^{-1}] \longrightarrow R((t^{-1})) \quad (10.4)$$

of the inclusion map; in particular,  $\gamma$  is injective.

Applying the functor  $- \otimes_{R_*[t]} R_*[t, t^{-1}]$  to a map as in (10.1) yields a map as in (10.3), by Lemma 2.5. Thus  $\gamma|_{R_*[t]}: R_*[t] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$  inverts all the maps (10.1) and factorises through a ring homomorphism  $\delta: \Omega_+^{-1}R_*[t] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$ . That is, the maps  $\alpha$  and  $\gamma$  fit into the commutative square diagram of Fig. 5 which, by Proposition 4.2, is a pushout square in the category of unital rings.

$$\begin{array}{ccc}
 R_*[t] & \xrightarrow{\alpha} & \Omega_+^{-1}R_*[t] \\
 \subset \downarrow \beta & \lrcorner & \delta \downarrow \\
 R_*[t, t^{-1}] & \xrightarrow{\gamma} & \Omega_+^{-1}R_*[t, t^{-1}]
 \end{array} \tag{10.5}$$

FIGURE 5. Pushout square of FREDHOLM localisations

**Theorem 10.6.** *Let  $R = R_*[t, t^{-1}]$  be a strongly  $\mathbb{Z}$ -graded ring, and let  $C^+$  be a bounded chain complex of finitely generated projective  $R_*[t]$ -modules. The following statements are equivalent:*

- (1) *The chain complex  $C^+$  is  $R_0$ -finitely dominated.*
- (2) *The induced chain complex  $C^+ \otimes_{R_*[t]} \Omega_+^{-1}R_*[t]$  is contractible.*
- (3) *The induced chain complex  $C^+ \otimes_{R_*[t]} \Omega_+^{-1}R_*[t, t^{-1}]$  is contractible.*

*Proof.* (1)  $\Rightarrow$  (2): Suppose that  $C^+$  is  $R_0$ -finitely dominated. For ease of notation we assume  $C_n^+ = 0$  for  $n < 1$ . By taking direct sum with contractible one-step complexes of the form  $P \xrightarrow{=} P$ , with  $P$  suitable finitely generated projective  $R_*[t]$ -modules, we obtain a new bounded chain complex  $A^+$  concentrated in non-negative chain levels, which is homotopy equivalent to  $C^+$  such that all chain modules  $A_n^+$  are finitely generated free over  $R_*[t]$ , with the possible exception of  $A_0^+$  which is finitely generated projective over  $R_*[t]$ . Explicitly, let  $N$  be maximal with  $C_N^+ \neq 0$ . We can choose finitely generated projective  $R_*[t]$ -module  $Q_N^+, Q_{N-1}^+, \dots, Q_1^+$ , in this order, such that  $C_n^+ \oplus Q_n^+ \oplus Q_{n+1}^+$  is finitely generated free ( $1 \leq n \leq N$ , with  $Q_k^+ = 0$  for  $k > N$ ); the bounded complex

$A^+$  can then take the form

$$\begin{array}{ccccccc}
Q_1^+ & \xleftarrow{=} & Q_1^+ & & Q_3^+ & \xleftarrow{=} & Q_3^+ & & Q_5^+ & \xleftarrow{=} & \dots \\
& & \oplus & & \oplus & & \oplus & & \oplus & & \\
C_1^+ & \xleftarrow{} & C_2^+ & \xleftarrow{} & C_3^+ & \xleftarrow{} & C_4^+ & \xleftarrow{} & \dots & & \\
& & \oplus & & \oplus & & \oplus & & \oplus & & \\
Q_2^+ & \xleftarrow{=} & Q_2^+ & & Q_4^+ & \xleftarrow{=} & Q_4^+ & & \dots & & 
\end{array}$$

so that  $C^+$  is a direct summand of  $A^+$ , and both the inclusion  $C^+ \longrightarrow A^+$  and the projection  $A^+ \longrightarrow C^+$  are homotopy equivalences.

For  $n > 0$  the module  $A_n^+ = C_n^+ \oplus Q_n^+ \oplus Q_{n+1}^+$  is finitely generated free. We choose a basis consisting of  $r_n$  elements, thereby identifying  $A_n^+$  with the finite direct sum  $\bigoplus_{r_n} R_*[t] = (R_*[t])^{r_n}$ . The  $n$ th chain module of the induced complex  $A^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is identified with  $R_*((t^{-1}))^{r_n}$ .

For  $n > 1$  the differential  $A_n^+ \longrightarrow A_{n-1}^+$  of  $A^+$  can be thought of as a matrix  $D_n^+$  with entries in  $R_*[t]$ . The differential  $D_1^+$  is the homomorphism given by projection onto  $A_0^+ = Q_1^+$ .

As  $C^+$  is  $R_*[t, t^{-1}]$ -finitely dominated, Theorem 8.1 ensures that the induced complex  $C^+ \otimes_{R_*[t]} R_*((t^{-1}))$  is contractible; we choose homomorphisms

$$\tau_n : C_n^+ \otimes_{R_*[t]} R_*((t^{-1})) \longrightarrow C_{n+1}^+ \otimes_{R_*[t]} R_*((t^{-1}))$$

forming a chain contraction. These maps give rise to a contraction  $\sigma^+$  of  $A^+ \otimes_{R_*[t]} R_*((t^{-1}))$ , by defining

$$\sigma_n : A_n^+ \otimes_{R_*[t]} R_*((t^{-1})) \longrightarrow A_{n+1}^+ \otimes_{R_*[t]} R_*((t^{-1}))$$

by the formula

$$\sigma_n^+ = \begin{cases} Q_1^+ \otimes_{R_*[t]} R_*((t^{-1})) \xrightarrow{\subseteq} A_1^+ \otimes_{R_*[t]} R_*((t^{-1})) & \text{for } n = 0, \\ \left( C_n^+ \oplus Q_n^+ \oplus Q_{n+1}^+ \right) \otimes_{R_*[t]} R_*((t^{-1})) \\ \xrightarrow{(\sigma_n, 0, \text{id})} \left( C_{n+1}^+ \oplus Q_{n+2}^+ \oplus Q_{n+1}^+ \right) \otimes_{R_*[t]} R_*((t^{-1})) & \text{for } n > 0. \end{cases}$$

Note that the map  $\sigma_0^+$  is defined over  $R_*[t]$ . For  $n > 0$  we think of  $\sigma_n^+$  as matrices with entries in  $R_*((t^{-1}))$  such that  $D_{n+1}^+ \cdot \sigma_n^+ + \sigma_{n-1}^+ \cdot D_n^+$  is a unit matrix of size  $r_n$ . We can truncate the entries of the matrices  $\sigma_n^+$  below at some suitable integer  $m \ll 0$  (not depending on  $n$ ) to obtain matrices  $S_n^+ = \text{tr}_m(\sigma_n^+)$  with entries in  $R_*[t, t^{-1}]$  such that  $E_n = D_{n+1}^+ \cdot S_n^+ + S_{n-1}^+ \cdot D_n^+$ , for  $n \geq 2$ , is the sum of a unit matrix, and a matrix the non-zero entries of

which have homogeneous components of strictly negative degree. Thus  $E_n$  is invertible over  $R_*(t^{-1})$  so that  $E_n \in \Omega_+$ . Similarly, writing  $S_0^+$  for the homomorphism  $\sigma_0^+$  we see that  $E_1 = D_2^+ \cdot S_1^+ + S_0^+ \cdot D_1^+$  and  $E_0 = D_1^+ \circ S_0^+$  are invertible in  $R_*(t^{-1})$  whence  $E_1, E_0 \in \Omega_+$  as well. Here we make use of the fact that  $\sigma_0^+ = S_0^+$  and  $D_1^+$  are defined over  $R_*[t]$ ; in fact  $E_0 = \text{id}_{Q_1}$ , and the matrix representing  $S_0^+ \cdot D_1^+$  has entries in  $R_*[t]$  and is hence unaffected by truncation.

We now define a new  $R_*[t]$ -module chain complex  $B^+$  by setting  $B_n^+ = (t^m R_*[t])^{r_n} = A_n^+ \otimes_{R_*[t]} t^m R_*[t]$ , with differentials given by the matrices  $D_n^+$  for  $n > 1$ , and the projection map onto the direct summand  $Q_1^+ \otimes_{R_*[t]} \otimes t^m R_*[t]$  for  $n = 1$ . The matrices  $S_n^+$  for  $n > 0$ , and the homomorphism  $S_0^+$ , define module homomorphisms  $A_n^+ \longrightarrow B_{n+1}^+$  constituting an  $(A^+, B^+)$ - $\alpha$ -proto-null homotopy, cf. §3, since  $E_n = D_{n+1}^+ \cdot S_n^+ + S_{n-1}^+ \cdot D_n^+$  is an element of  $\Omega_+$  as explained above. Here  $\alpha: R_*[t] \longrightarrow \Omega_+ R_*[t]$  is the localisation map as in (10.5). It follows that  $A^+ \otimes_{R_*[t]} \Omega_+^{-1} R_*[t]$  is contractible by Lemma 3.1, hence so is  $C^+ \otimes_{R_*[t]} \Omega_+^{-1} R_*[t]$ .

(2)  $\Rightarrow$  (3): Immediate from the factorisation

$$R_*[t] \xrightarrow{\alpha} \Omega_+^{-1} R_*[t] \longrightarrow \Omega_+^{-1} R_*[t, t^{-1}]$$

of  $\gamma$ , see (10.5) in Fig. 5.

(3)  $\Rightarrow$  (1): Immediate from the factorisation (10.4) and Theorem 8.1.  $\square$

**Theorem 10.7** (Universal property of  $\Omega_+^{-1} R_*[t]$ ). *Suppose that  $R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring. The localisation  $\lambda: R_*[t] \longrightarrow \Omega_+^{-1} R_*[t]$  is the universal  $R_*[t]$ -ring making  $R_0$ -finitely dominated chain complexes contractible. That is, suppose that  $f: R_*[t] \longrightarrow S$  is an  $R_*[t]$ -ring such that for every bounded complex of finitely generated projective  $R_*[t]$ -modules  $C^+$  which is  $R_0$ -finitely dominated, the complex  $C^+ \otimes_{R_*[t]} S$  is contractible. Then there is a factorisation  $R_*[t] \xrightarrow{\lambda} \Omega_+^{-1} R_*[t] \xrightarrow{\eta} S$  of  $f$ , with a uniquely determined ring homomorphism  $\eta$ .*

*Proof.* It was shown in Theorem 10.6 above that  $\Omega_+^{-1} R_*[t]$  makes  $R_0$ -finitely dominated chain complexes contractible. Thus it is enough to show that  $f$  inverts the maps  $\mu(A^+, m)$  of (10.1) for any  $A^+ \in \Omega_+$  and any suitable  $m \in \mathbb{Z}$ . By definition of  $\Omega_+$  the complex  $\mu(A^+, m)$  is  $R_0$ -finitely dominated so that, by hypothesis on  $f$ , the complex  $\mu(A^+, m) \otimes_{R_*[t]} S$  is contractible. This says precisely that  $f$  inverts the map  $\mu(A^+, m)$ .  $\square$

One can also show that *the localisation*  $\lambda: R_*[t, t^{-1}] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$  is the universal  $R_*[t, t^{-1}]$ -ring making  $R_0$ -finitely dominated, bounded chain complexes of finitely generated projective  $R_*[t]$ -modules complexes contractible.

We finish with proving that  $\delta: \Omega_+^{-1}R_*[t] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$  is an isomorphism if  $R_*[t, t^{-1}]$  contains a homogeneous unit of non-zero degree.

**Proposition 10.8.** *Suppose that  $R = R_*[t, t^{-1}]$  is a strongly  $\mathbb{Z}$ -graded ring. Suppose there exists a homogeneous unit of positive degree in  $R_*[t, t^{-1}]$ . Then there is an injective ring homomorphism  $\iota: R_*[t, t^{-1}] \longrightarrow \Omega_+^{-1}R_*[t]$  with  $\iota\beta = \alpha$ , and  $\delta: \Omega_+^{-1}R_*[t] \longrightarrow \Omega_+^{-1}R_*[t, t^{-1}]$  is an isomorphism satisfying  $\delta\iota = \gamma$ .*

*Proof.* Let  $u \in R_d \cap R_*[t, t^{-1}]^\times$ , with  $d > 0$ . Then the  $1 \times 1$ -matrix  $(u)$  is an  $R_*[t]$ -FREDHOLM matrix since the cokernel of the map

$$R_*[t] \longrightarrow R_*[t], \quad r \mapsto ur$$

is the finitely generated projective  $R_0$ -module  $\bigoplus_0^{d-1} R_j$ . The induced map

$$\Omega_+^{-1}R_*[t] \longrightarrow \Omega_+^{-1}R_*[t]$$

is given by multiplication with  $\alpha(u) \in \Omega_+^{-1}R_*[t]$ . Since the induced map is an isomorphism,  $\alpha(u)$  is invertible in  $\Omega_+^{-1}R_*[t]$ .

Given any  $x \in R_*[t, t^{-1}]$  there exists  $k \geq 0$  with  $u^k x \in R_*[t]$  and thus  $\alpha(u^k x) \in \Omega_+^{-1}R_*[t]$ ; we define  $\iota(x) = \alpha(u)^{-k} \cdot \alpha(u^k x) \in \Omega_+^{-1}R_*[t]$ . The element  $\iota(x)$  does not depend on the choice of  $k$ , for if  $\ell > k$  we have

$$\alpha(u)^{-\ell} \cdot \alpha(u^\ell x) = \alpha(u)^{-k} \alpha(u)^{-\ell+k} \cdot \alpha(u^{\ell-k} u^k x) = \alpha(u)^{-k} \cdot \alpha(u^k x),$$

since  $u^{\ell-k} \in R_*[t]$  and since  $\alpha$  is a ring homomorphism. Note that  $\iota(x) = \alpha(x)$  for  $x \in R_*[t]$ , and that  $\iota(u^{-1}) = \alpha(u)^{-1}$ .

Suppose that  $x \in R_*[t, t^{-1}]$  and  $k, \ell \geq 0$  are such that  $u^k x u^{-\ell} \in R_*[t]$ . Then  $\alpha(u^k x u^{-\ell}) = \alpha(u^k x) \alpha(u)^{-\ell}$ , since both sides equal  $\alpha(u^k x)$  after multiplication with  $\alpha(u)^\ell$ . Consequently, for  $x, y \in R_*[t, t^{-1}]$  and  $k, \ell \geq 0$  with  $u^\ell y, u^k x u^{-\ell} \in R_*[t]$  we calculate

$$\begin{aligned} \iota(xy) &= \iota(xu^{-\ell}u^\ell y) \\ &= \alpha(u)^{-k} \cdot \alpha(u^k x u^{-\ell} u^\ell y) \\ &= \alpha(u)^{-k} \cdot \alpha(u^k x u^{-\ell}) \cdot \alpha(u^\ell y) \\ &= \alpha(u)^{-k} \cdot \alpha(u^k x) \cdot \alpha(u)^{-\ell} \cdot \alpha(u^\ell y) = \iota(x) \cdot \iota(y). \end{aligned}$$

Since  $\iota$  is clearly additive, the map  $\iota : R_*[t, t^{-1}] \longrightarrow \Omega_+^{-1}R_*[t]$  is thus a ring homomorphism. Moreover,  $\iota$  is injective as  $\iota(x) = \alpha(u)^{-k} \cdot \alpha(u^k x)$  vanishes if and only if  $\alpha(u^k x)$  vanishes. It follows from Lemmas 2.6 and 4.3 that the ring homomorphism  $\delta$  is an isomorphism and satisfies  $\delta\iota = \gamma$ .  $\square$
